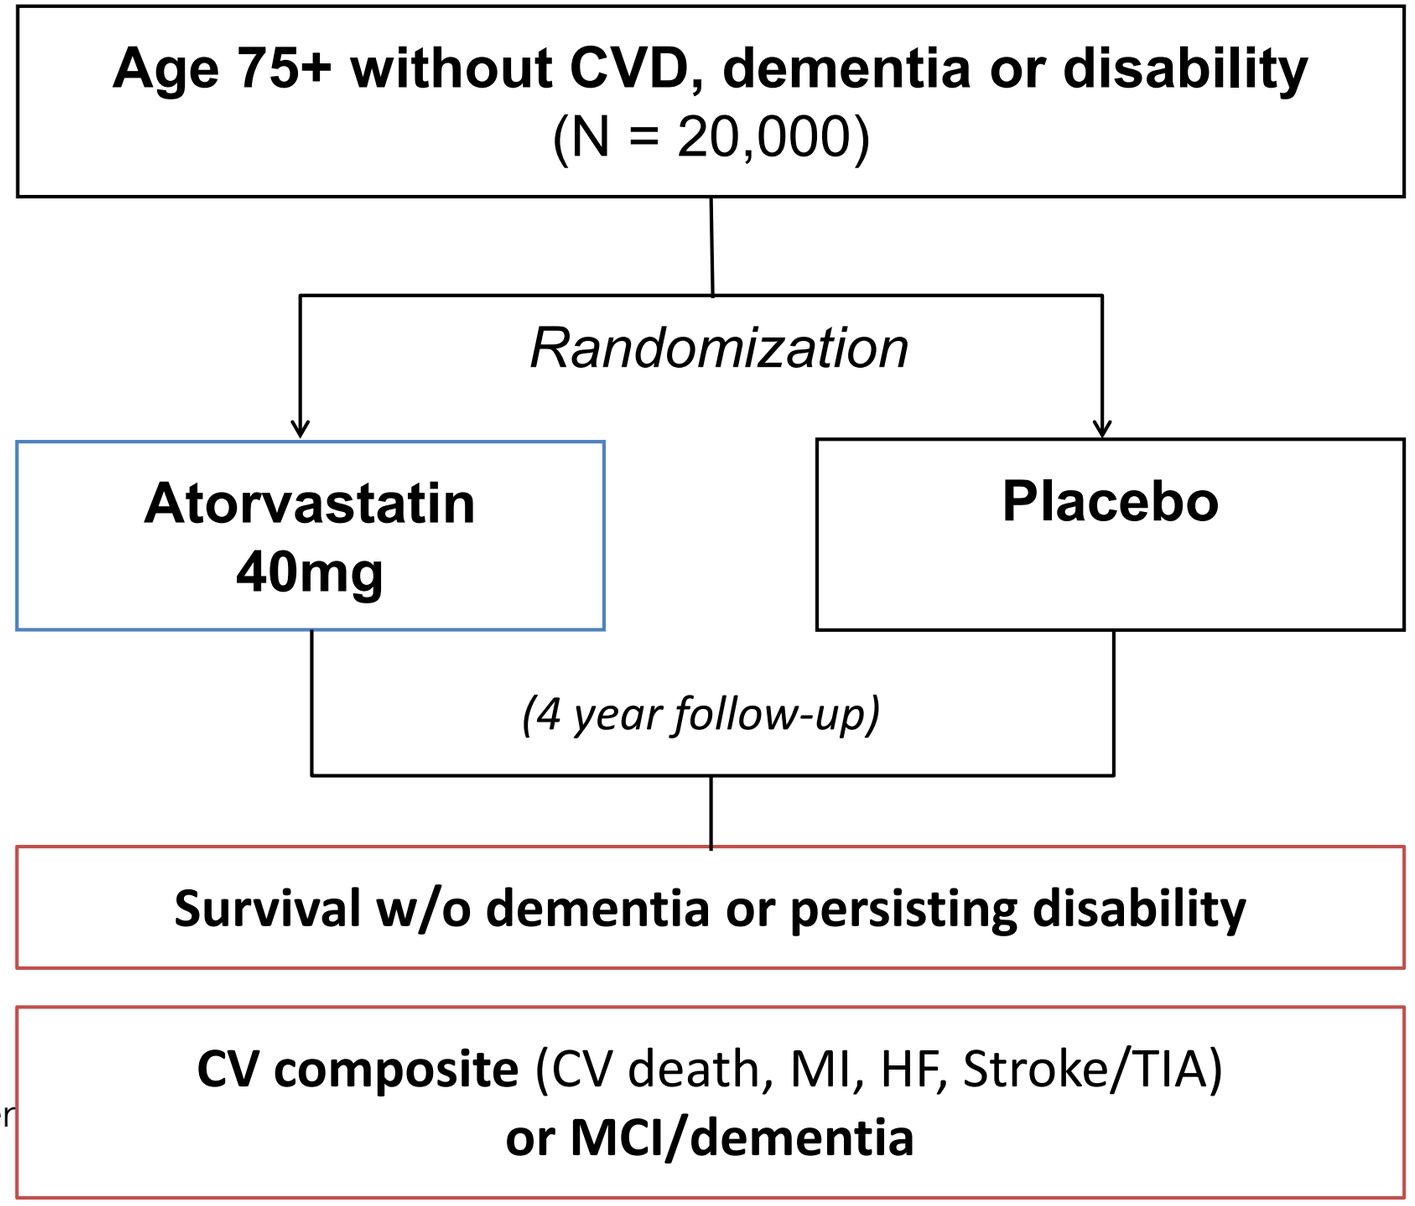
CENTER ON AGING
THE UNIVERSITY OF UTAH

PREVENTABLE

PRagmatic EValuation of evENTs And Benefits of Lipid-lowering in oldEr adults

Participants will:

- Be randomly assigned to atorvastatin 40 mg daily or matching placebo.
- Be followed through yearly phone calls for close to four years.
- Receive cognitive and physical function testing at screening, over the phone, and at home, if triggered.



CENTER ON AGING
THE UNIVERSITY OF UTAH

INFLAMMATION, COGNITIVE IMPAIRMENT AND DEPRESSIVE SYMPTOMS

Mark Rapaport, MD and team

- One-third of people with mild cognitive impairment (MCI) have comorbid depressive symptoms.
- Both MCI and depression are major ADRD predictors.
- Chronic inflammation may be a common mechanism underlying both
- Treatment with high-dose omega-3 fatty acids (n-3) has been shown to reduce systemic inflammation

HYPOTHESES

- Treatment with n-3 eicosapentaenoic acid (EPA) 4 gm/day vs. placebo will:
  - result in significantly better mean cognitive change scores
  - significantly reduce depressive symptom severity levels
  - significantly decrease inflammation

QUESTIONS…

About our logo…

The bristlecone pine tree (Pinus longaeva) - the earth's oldest inhabitant with a life span of 4,000 years - is found only in Utah and five other western states. Its extraordinary longevity and ability to adapt and survive in extremely harsh environmental conditions above 10,000 feet embodies the investigative spirit and mission of the Utah Center on Aging.

Objectively Measured Sedentary Behavior and Physical Activity in PREVENTABLE Study

R01AG074592

Srinivasan Beddhu, MD
Professor of Internal Medicine
SLC VA Healthcare System and
University of Utah School of Medicine
Salt Lake City, UT

Sedentary Behavior

Classification of physical activity based on intensity levels

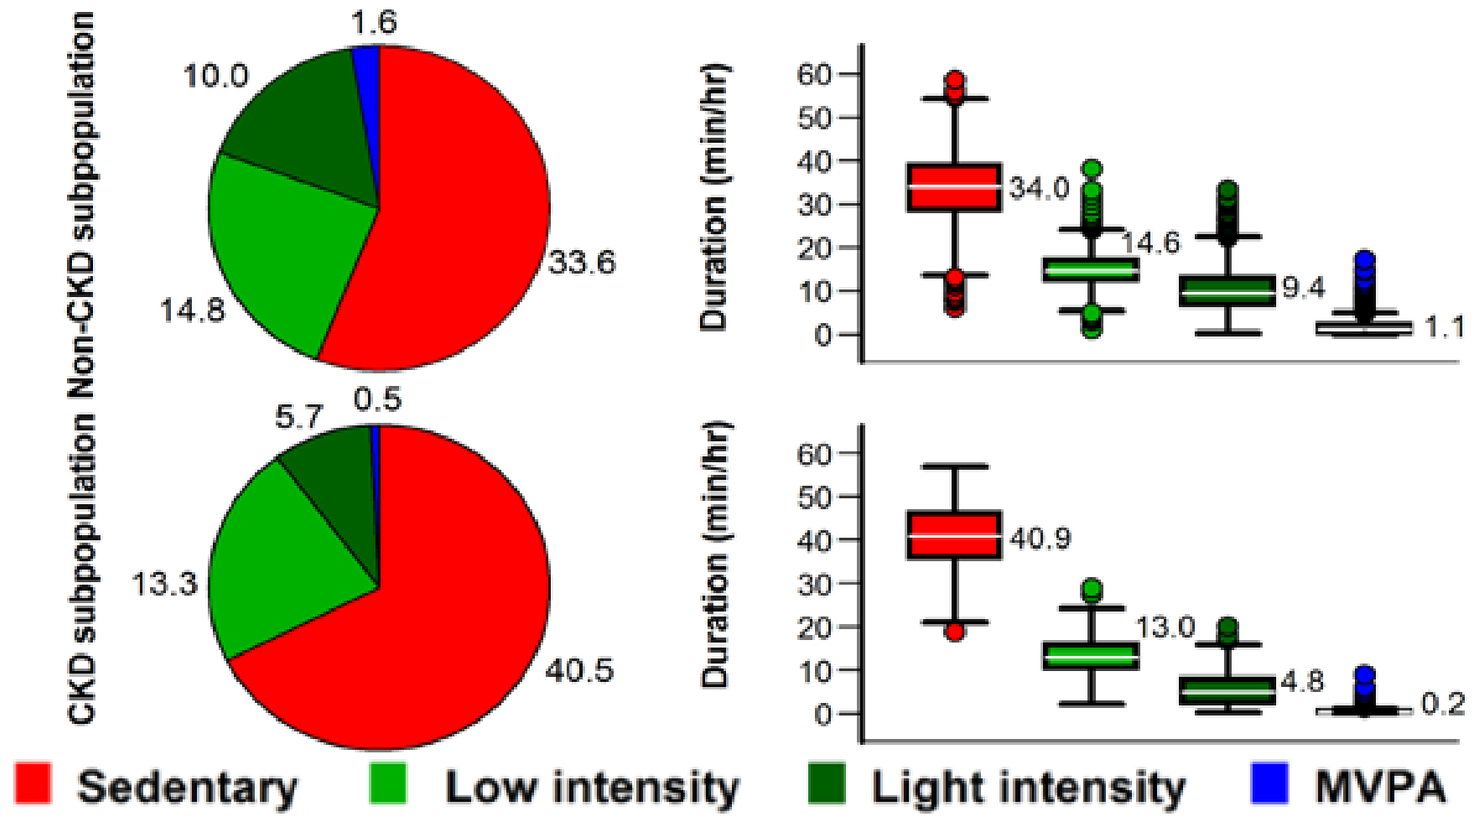
Type	Example	MET*
Sedentary	Sitting and watching TV	<1.5
Very light intensity	Standing, walking very slow (< 2.0 mph)	1.5-1.9
Light intensity	Casual walking (2 to 2.5 mph), light gardening	2.0-2.9
Moderate intensity	Brisk walking (~ 3.5 mph)	3.0-5.9
Vigorous intensity	Running, lifting heavy weights	≥6.0

***Based on 2011 Compendium of Physical Activities[1]**

Sedentary behavior

- Sedentary behavior is engaging in activities in the seated or lying position that barely raise the energy expenditure above this level (~ 1.0-1.4 METs)
- Distinct from “physical inactivity” i.e., not achieving weekly goal
- One can exercise for 150 min/ week and sit for the rest of the 98% of awake time (2.5 / (16x7))
- There is a large body of literature on physical inactivity and dementia risk but not on the associations of sedentary behavior with MCI/ dementia

Distribution of physical activity intensity durations per 60 minutes of awake time in non-CKD and CKD in NHANES



Beddhu et al. CJASN. 2015 Jul 7;10(7):1145-53

Hazard ratios of death per 2 min/hr trade-off of sedentary duration with equal duration of light activity or MVPA duration*

	↑ 2 min/hr of light activity duration HR (95% CI, p)**	↑ 2 min/hr of MVPA duration HR (95% CI, p)***
Entire cohort	0.67 (0.48, 0.93, p = 0.02)	0.80 (0.42, 1.51, p = 0.46)
CKD subgroup	0.59 (0.35, 0.98, p = 0.04)	0.46 (0.09, 2.45, p = 0.34)

*In Cox regression models taking survey design into account and adjusted for age, gender, race, education, smoke, alcohol use, lung disease, mobility limitations

**Mortality risk associated with each 2 min/hr decrement in a sedentary duration with a corresponding 2 min/hr increment in light activity duration while controlling for low intensity and MVPA durations

**Mortality risk associated with each 2 min/hr decrement in a sedentary duration with a corresponding 2 min/hr increment in MVPA duration while controlling for low intensity and light intensity activity durations

Beddhu et al. CJASN. 2015 Jul 7;10(7):1145-53

Ancillary study team

Principal Investigator
Srinivasan Beddhu, MD, University of Utah

PREVENTABLE Affiliated investigator
Mark Supiano, MD, University of Utah School of Medicine
Jeff Williamson, MD, Wake Forest University
Walter Ambrosius, PhD, Wake Forest University

Collaborators:
Tom Greene, PhD, University of Utah
Kate Lyden, PhD, Colorado State University
Aditi Gupta, MD, University of Kansas Medical Center

SPECIFIC AIM 1

- To examine the associations of sedentary duration with a composite of incident mild cognitive impairment (MCI) or dementia in older persons.
- To examine associations of ‘trade-off’ of 5 min/hr of sedentary duration to 5 min/hr of stepping duration with a composite of incident mild cognitive impairment (MCI) or dementia in older persons.

Hypothesis: Longer sedentary duration promotes faster decline of cognitive function decline; whereas, trade-off of sedentary duration for stepping duration is associated with slower cognitive function decline in older persons.

SPECIFIC AIM 2

- To examine whether PREVENTABLE intervention (atorvastatin compared to placebo) impacts on

A. the number of steps/day and

B. Sedentary and stepping durations/ day.

Hypothesis: Randomization to atorvastatin will result in lower incidence of physical disability which will associate with lower sedentary duration and higher physical activity levels relative to older persons randomized to placebo.

Ancillary study procedures

Visit (Month)/	Within 3 months of Randomization	Month 12	Month 36
Activity monitor training/education	X		
Wearing of activity monitor for 7 days	X	X	X
Completing wear time diary for 7 days	X	X	X
Sedentary Behavior Questionnaire	X	X	X

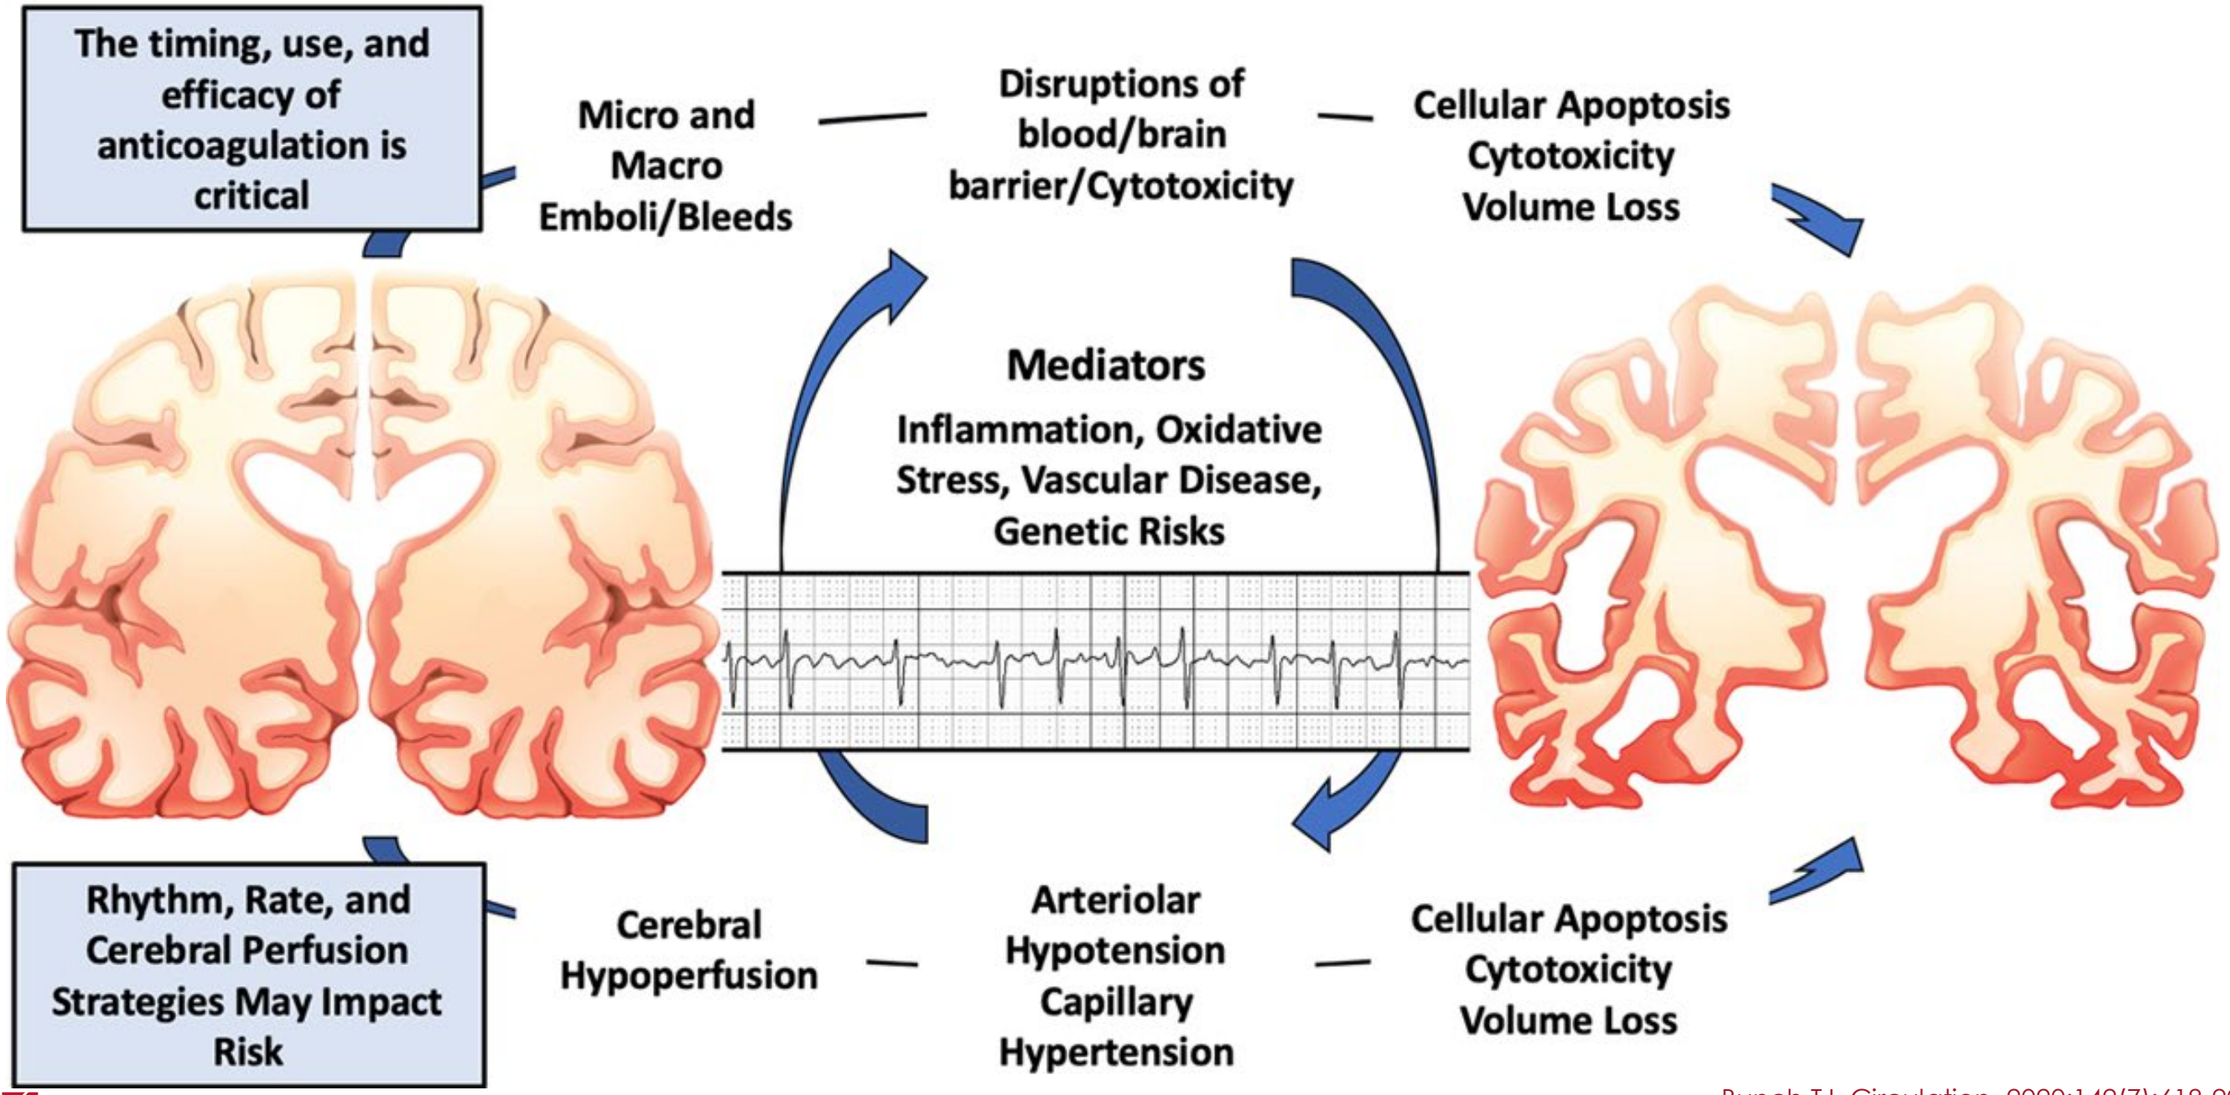
POTENTIAL MECHANISMS: AF & COGNITION

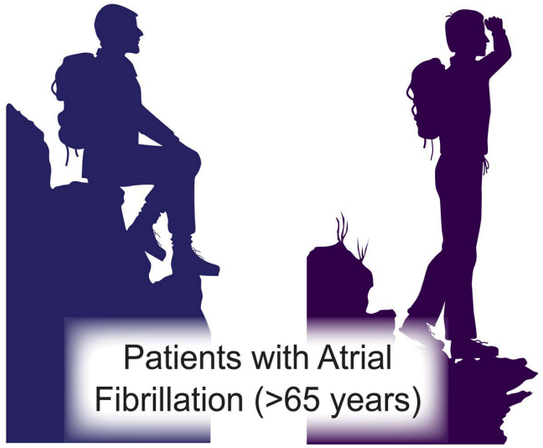


Bunch TJ. Circulation. 2020;142(7):618-20.

AF & STROKE (& COGNITION)

Incidence of Stroke is Directly Dependent on Diagnostic Methods Used and Traditional Stroke Symptoms Correlate Inconsistently with Infarcts on MRI

Different Viewpoints/Perspectives



Clinical Stroke/TIA Symptoms at 2 years

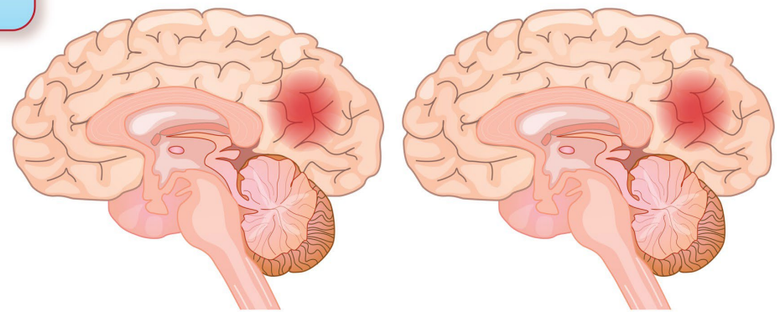
2.3% Incidence

Brain MRI at 2 Years

5.5% Incidence

2.4x Increase

Are "Silent" Strokes Really Silent?



Traditional Clinical Symptoms

No Traditional Clinical Symptoms

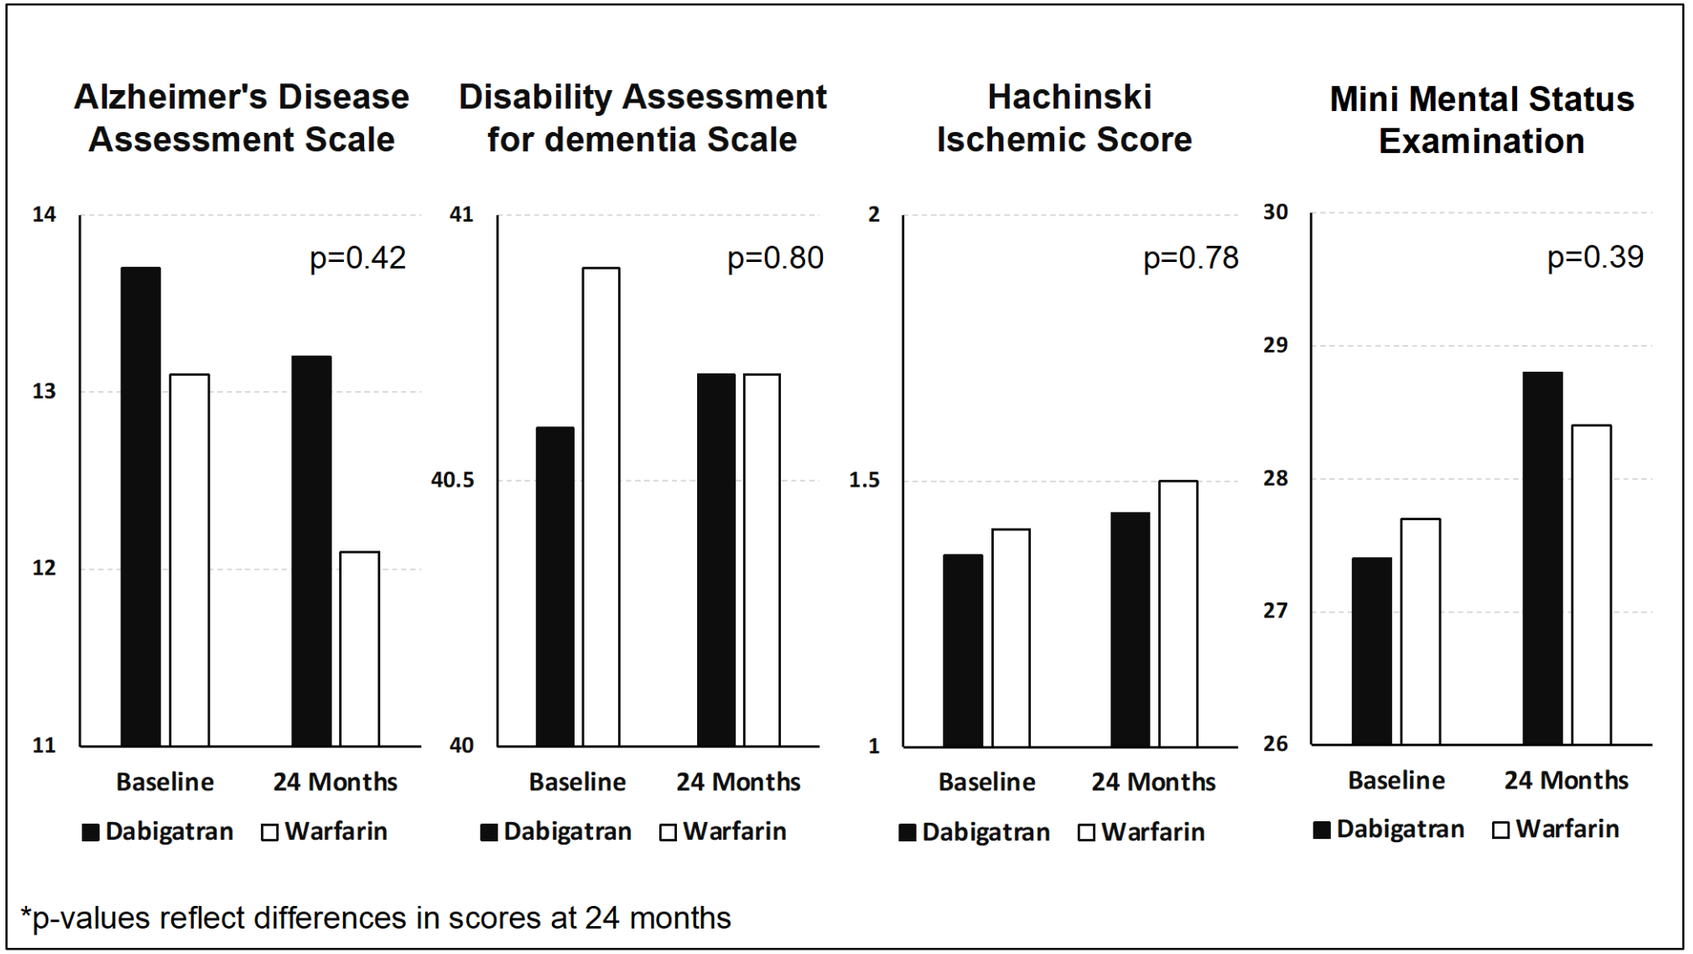
Deficiencies of cognitive operations, semantic memory, language production and mental flexibility are present with testing at 2 years

Brain Injury in Patients with Atrial Fibrillation

1. "Clinical" Stroke/TIA diagnosis significantly underestimated incidence
2. "Silent" Strokes is a misnomer and these infarcts impact function when targeted testing is used

Bunch TJ, Steinberg BA. Eur Heart J. 2022 Feb 18;ehab900.

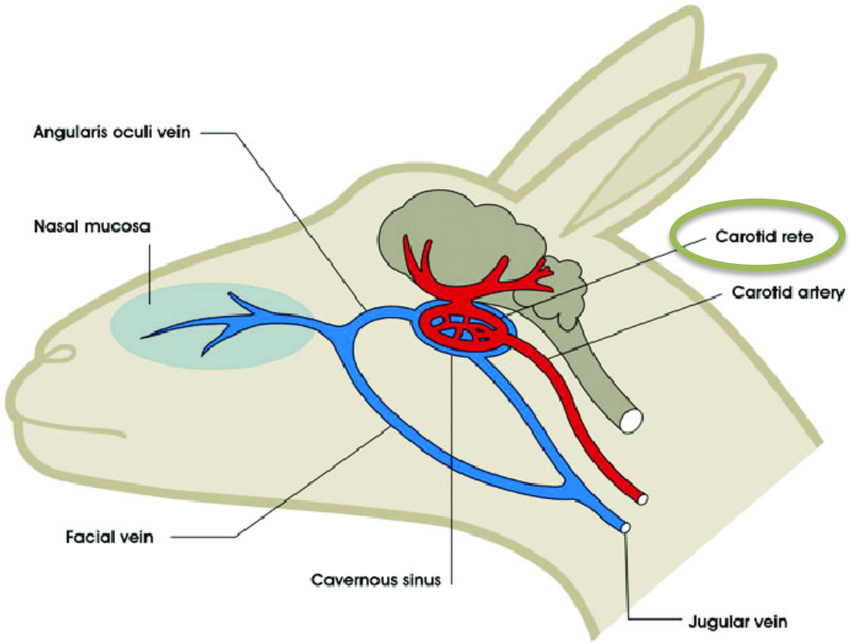
COGNITIVE DECLINE AND DEMENTIA IN PATIENTS WITH NON-VALVULAR ATRIAL FIBRILLATION (CAF) TRIAL



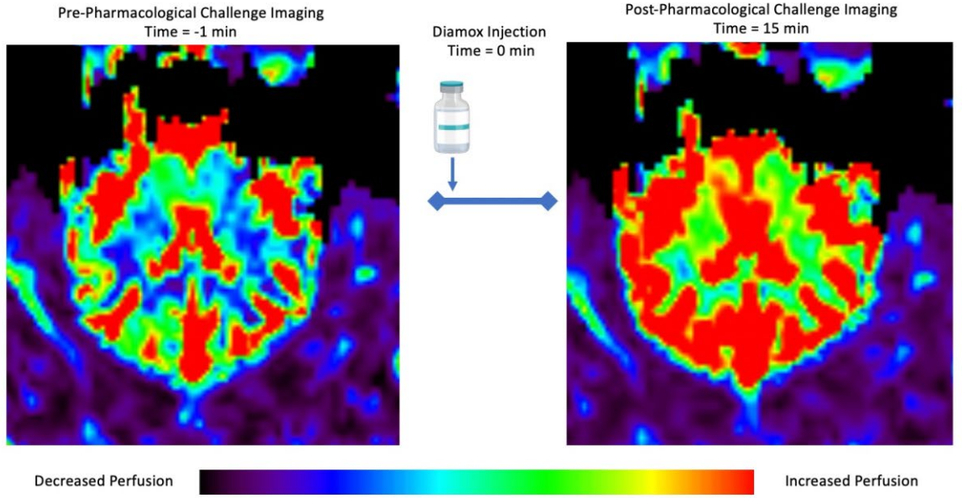
*p-values reflect differences in scores at 24 months

Bunch TJ, et al. Submitted.

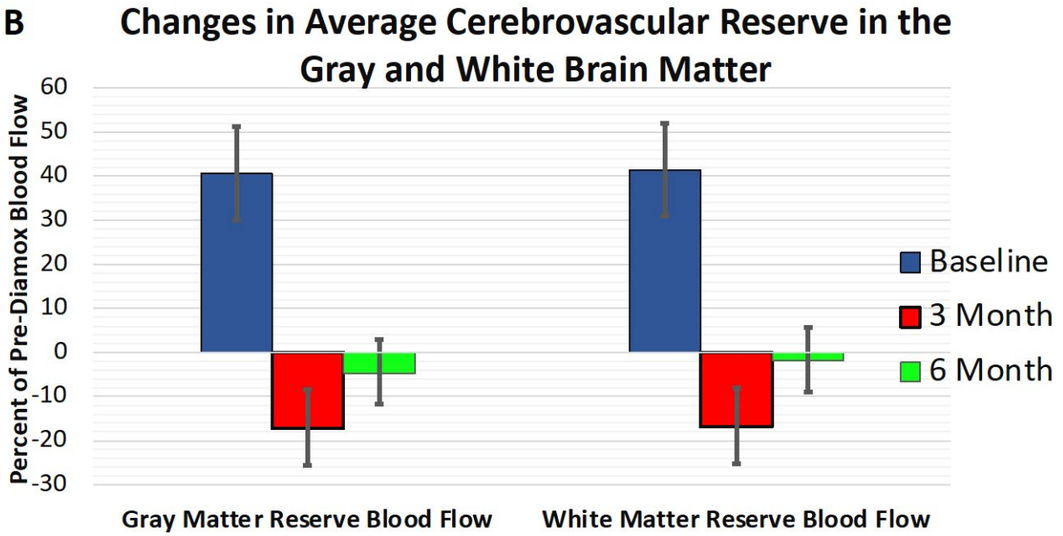
CEREBROVASCULAR RESERVE IN AF (CANINE)



A



B



Strauss W et at. Conservation Physiology. 2017;5(1), cow078.
Zenger B…Bunch TJ. JACC EP. In Revision.

SUMMARY: AF & COGNITION

- Causal relationship beyond stroke
  - Mechnism unclear (?cerebrovascular reserve)

- Future directions
  - Additional animal work (mechanism)
  - Patient Reported Outcomes vis-à-vis memory, cognition
    - Not-so-'silent' infarcts
  - Potential interventions (e.g., 'novel-er' blood thinners, ablation)

Balance, Mobility, and Concussion in Older Adults

University of Utah Center on Aging

15th Annual Research Retreat

May 26, 2022

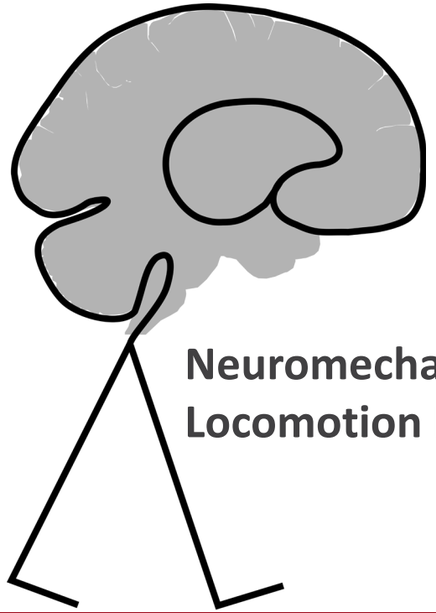
Peter Fino, PhD

Assistant Professor

Health and Kinesiology

College of Health

University of Utah

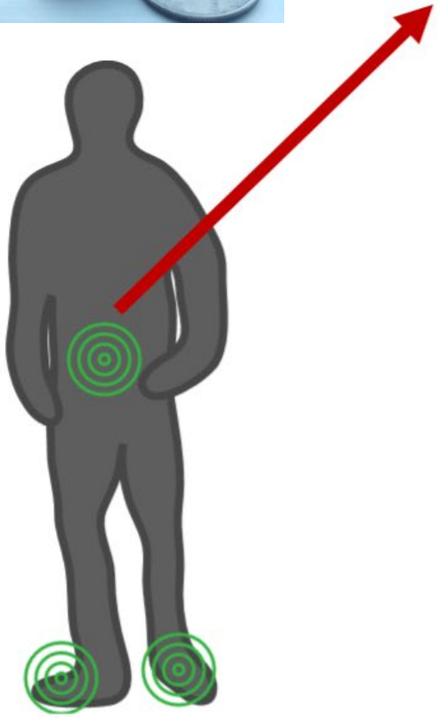


Neuromechanics & Applied Locomotion Laboratory

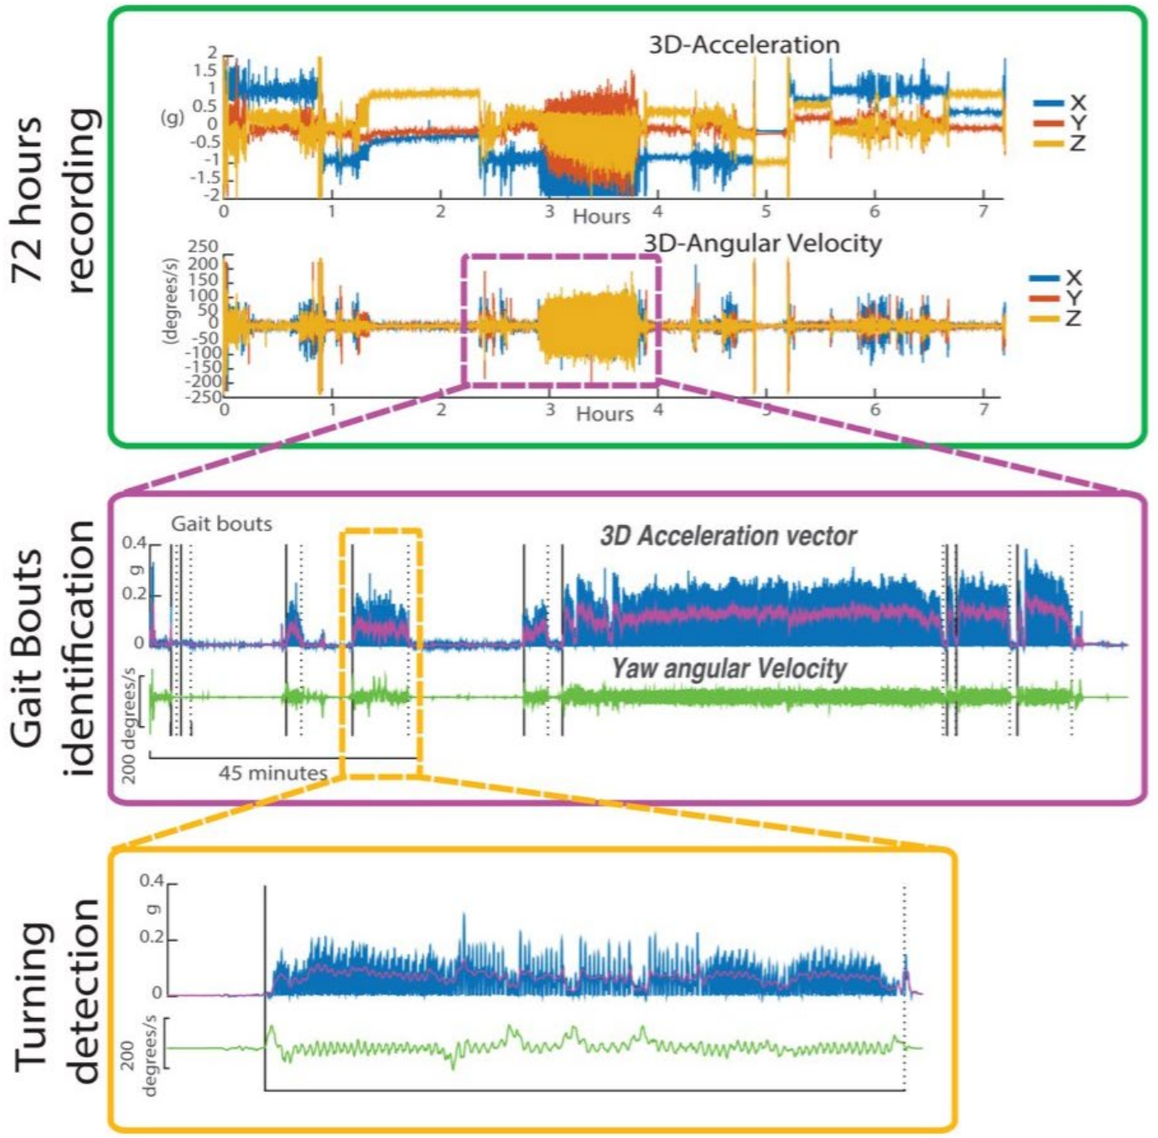
My research focuses on quantifying balance and mobility during functionally relevant tasks to inform rehabilitative care and clinical decisions

Ecologically relevant and real-world tasks

Wearables / clinically deployable tools

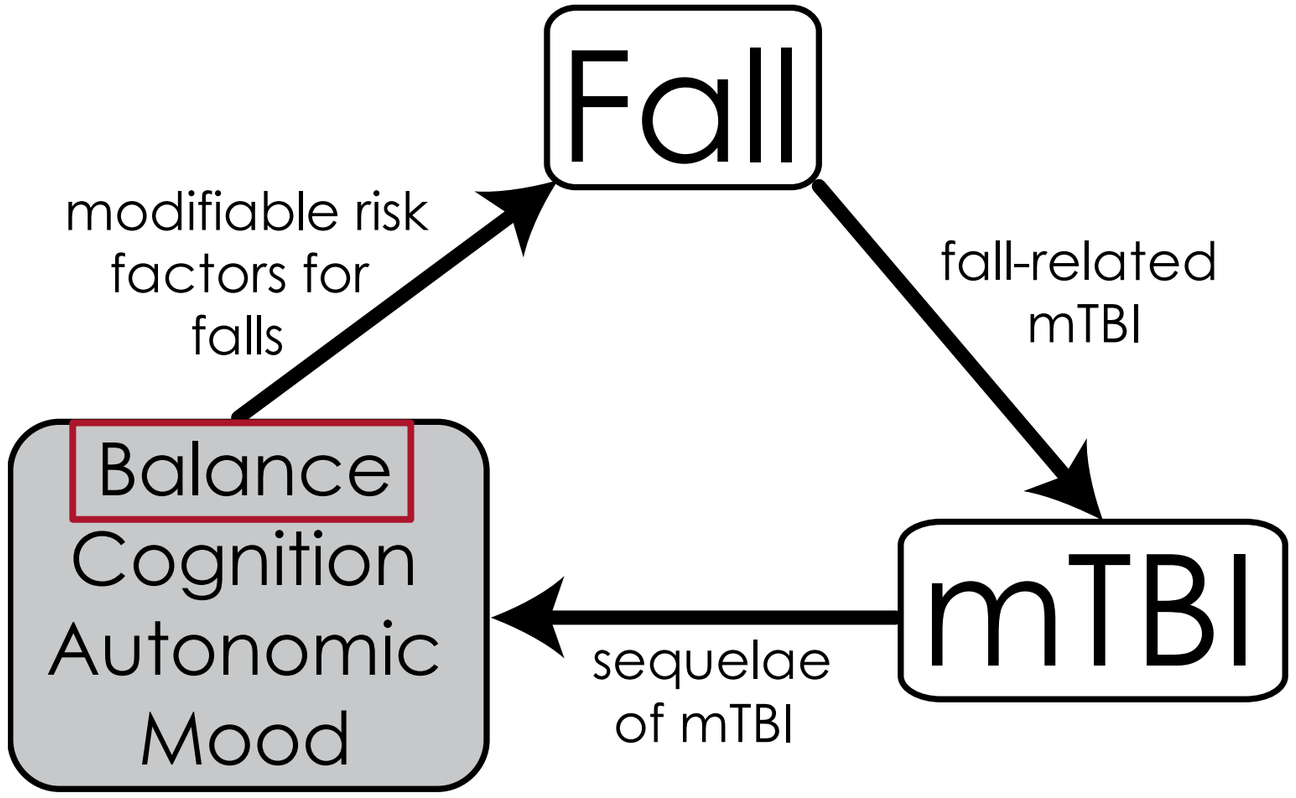


Return-to-life after concussion



Older adults suffer more concussions (i.e., mTBIs) than any other age group and the majority are caused by falls[1]

Greater mortality from nervous system (e.g., PD) and dementia-related disorders[3]



1. Taylor et al. MMWR Surveill Summ 2017; 2. Komisar et al. BMC Geriatrics 2022
3. Harrison-Felix et al. J Head Trauma Rehabil 2012

We have very little knowledge of the effects of concussions in older adults

Young adults

≠

Older adults

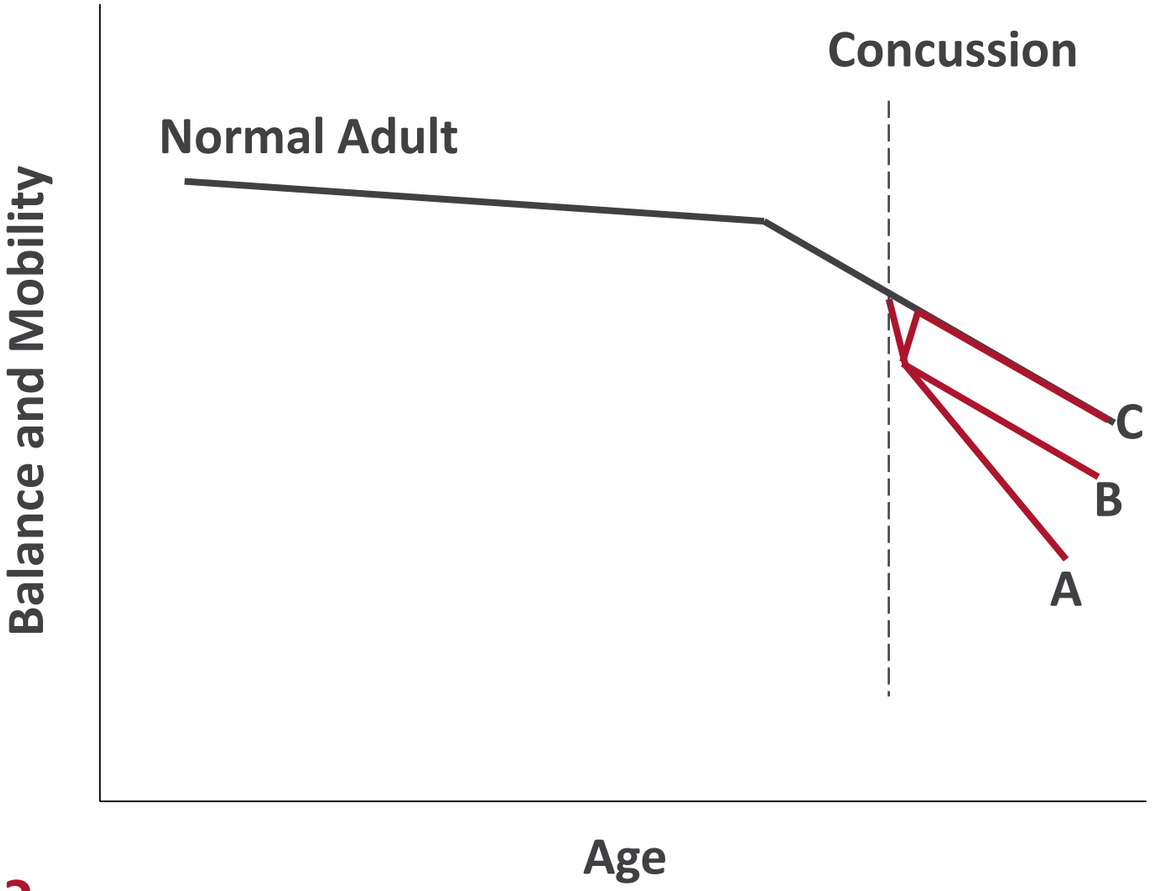
Review = Systematic review or Meta-analysis
Retro = Association with retrospective falls
Pro = Association with prospective falls

Between = Comparison to healthy subjects
Within = Comparison to baseline or pre-injury

Step 1: Establish the ‘natural history of concussion’ in older adults
Step 1B: Establish guidelines for care for older adults after concussion

What factors influence recovery?

- Neuromuscular
- Cognitive
- Physiological
- Psychosocial
- Healthcare resources
- Social determinants
- Genetic



Can we change someone’s trajectory?

Concussions are complex - our translational research is only possible because of interdisciplinary perspectives at Utah

Optimizing Antihypertensive Treatment in 2022 to Prevent Cardiovascular Disease and Dementia: Lessons Using Pharmacoepidemiology

Adam Bress, Pharm.D., M.S.
Associate Professor

Department of Population Health Sciences
Division of Health System Innovation and Research
University of Utah School of Medicine
VA Salt Lake Health Care System

@adambress

May 25, 2022, Center on Aging Cognitive Resilience Retreat, University of Utah

Background: blood pressure & cognitive outcomes

- Hypertension, particularly in mid-life, is a modifiable risk factor for cognitive decline and dementia
  - Hypertension affects ~50% of the US adult population

- Meta-analyses of BP-lowering RCTs show that lowering BP with antihypertensive medication reduces risk of cognitive outcomes, yet precise causal mechanisms remain unclear

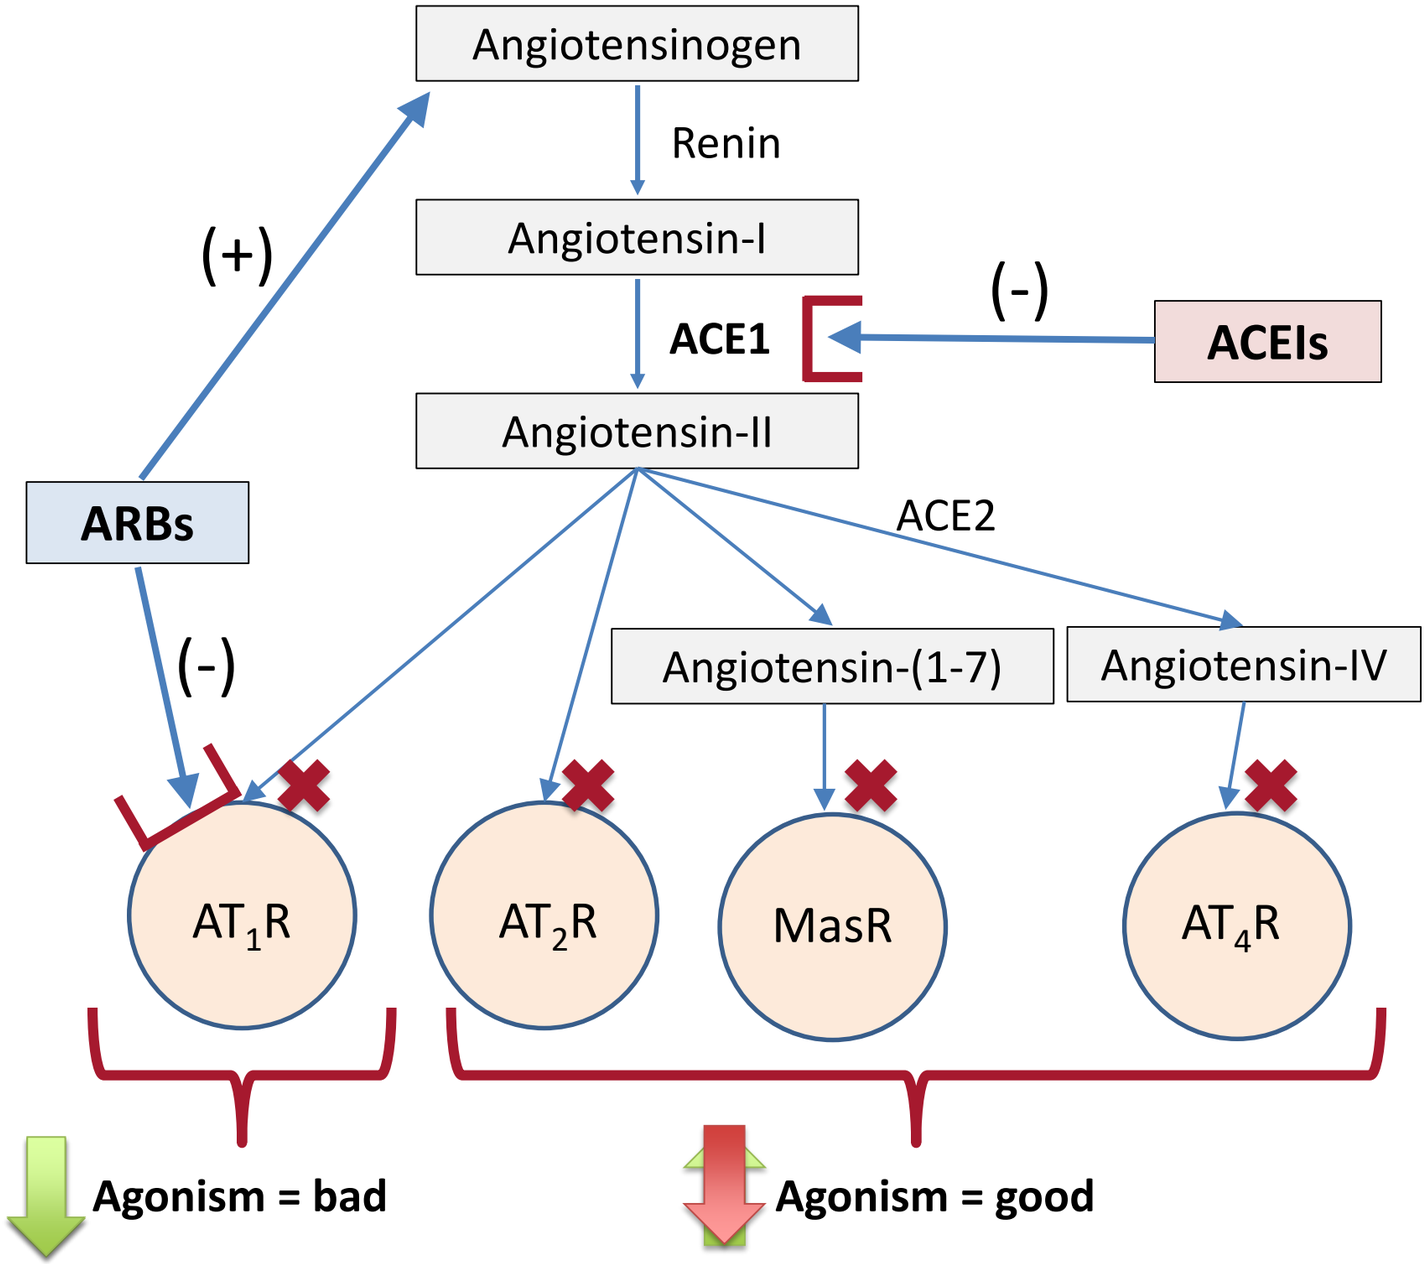
- Whether cognitive benefits are achieved via BP reduction alone or via direct effects of antihypertensive medications on the brain, independent of BP-lowering effects is unclear

Should we be using ARBs routinely over ACEIs?

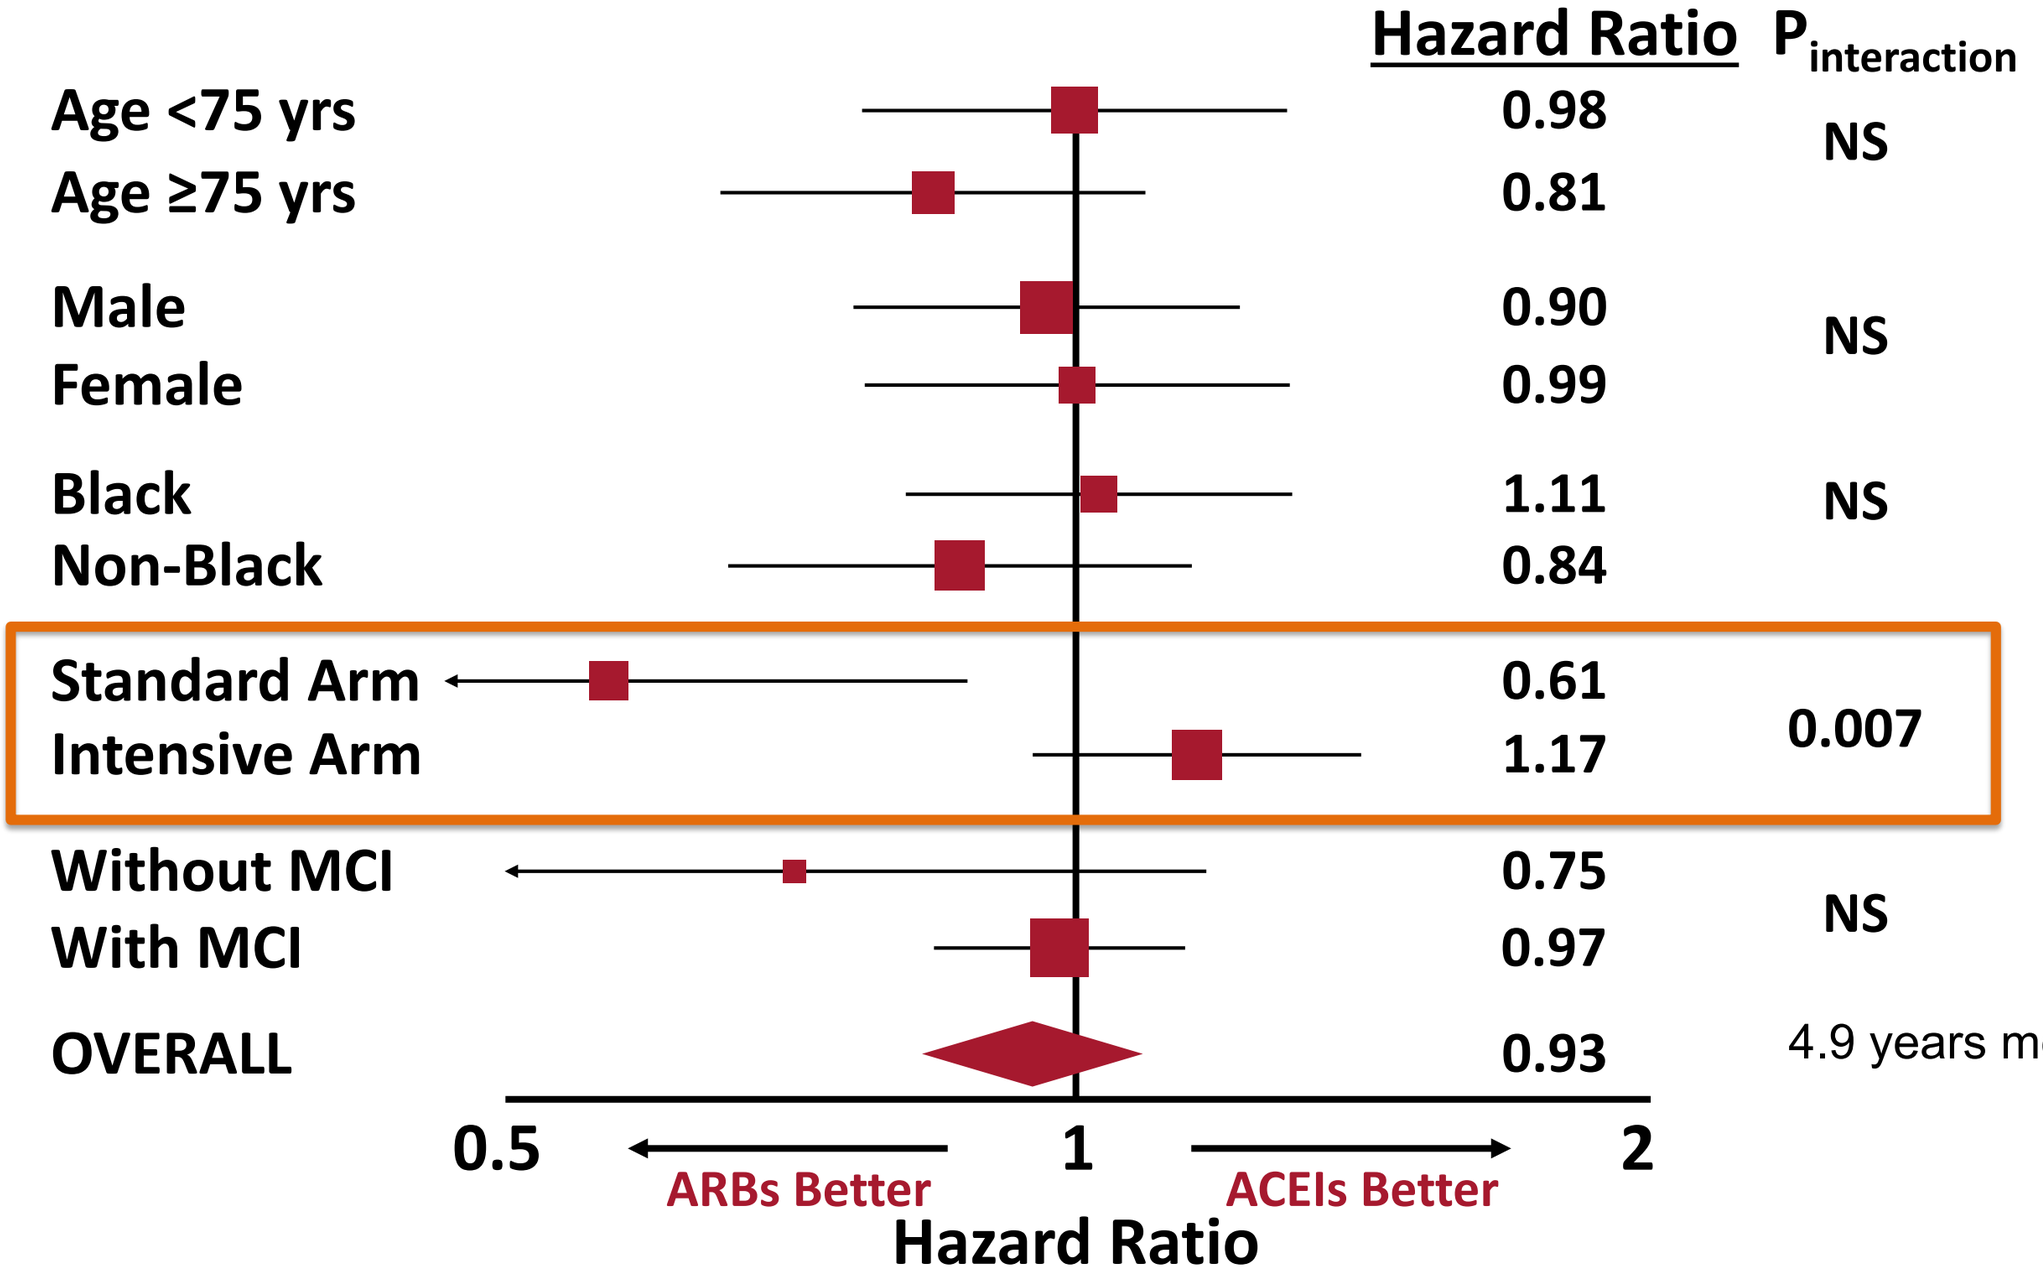
- Angiotensin II receptor blockers (ARBs) and angiotensin-converting enzyme inhibitors (ACEIs) are used by approximately 33 million US adults
  - ~20 million taking an ACEI
  - ~13 million taking an ARB
- Current guidelines recommend ARBs and ACEIs interchangeably for hypertension treatment
- Notably, ARBs and ACEIs work distinctly on the renin-angiotensin system (RAS)

Proposed mechanism of differential effects of ARBs vs. ACEIs?

- ARBs bind AT1 receptors, downstream from where ACEIs act
- Shifting circulating Ang II to bind/stimulate AT2, AT4 Mas receptors leading to:
  - ⬇ oxidative stress, neuroinflammation, and endothelial dysfunction
  - ⬆ cerebral hypoperfusion and potentially memory-enhancing effects
- In contrast, by inhibiting conversion of Ang I to Ang II, ACEIs ⬇ circulating Ang II
- Thereby, ⬇ stimulation of AT1 and AT2/AT4 receptors and ⬇ potential for beneficial effects of agonism at AT2/4 receptors



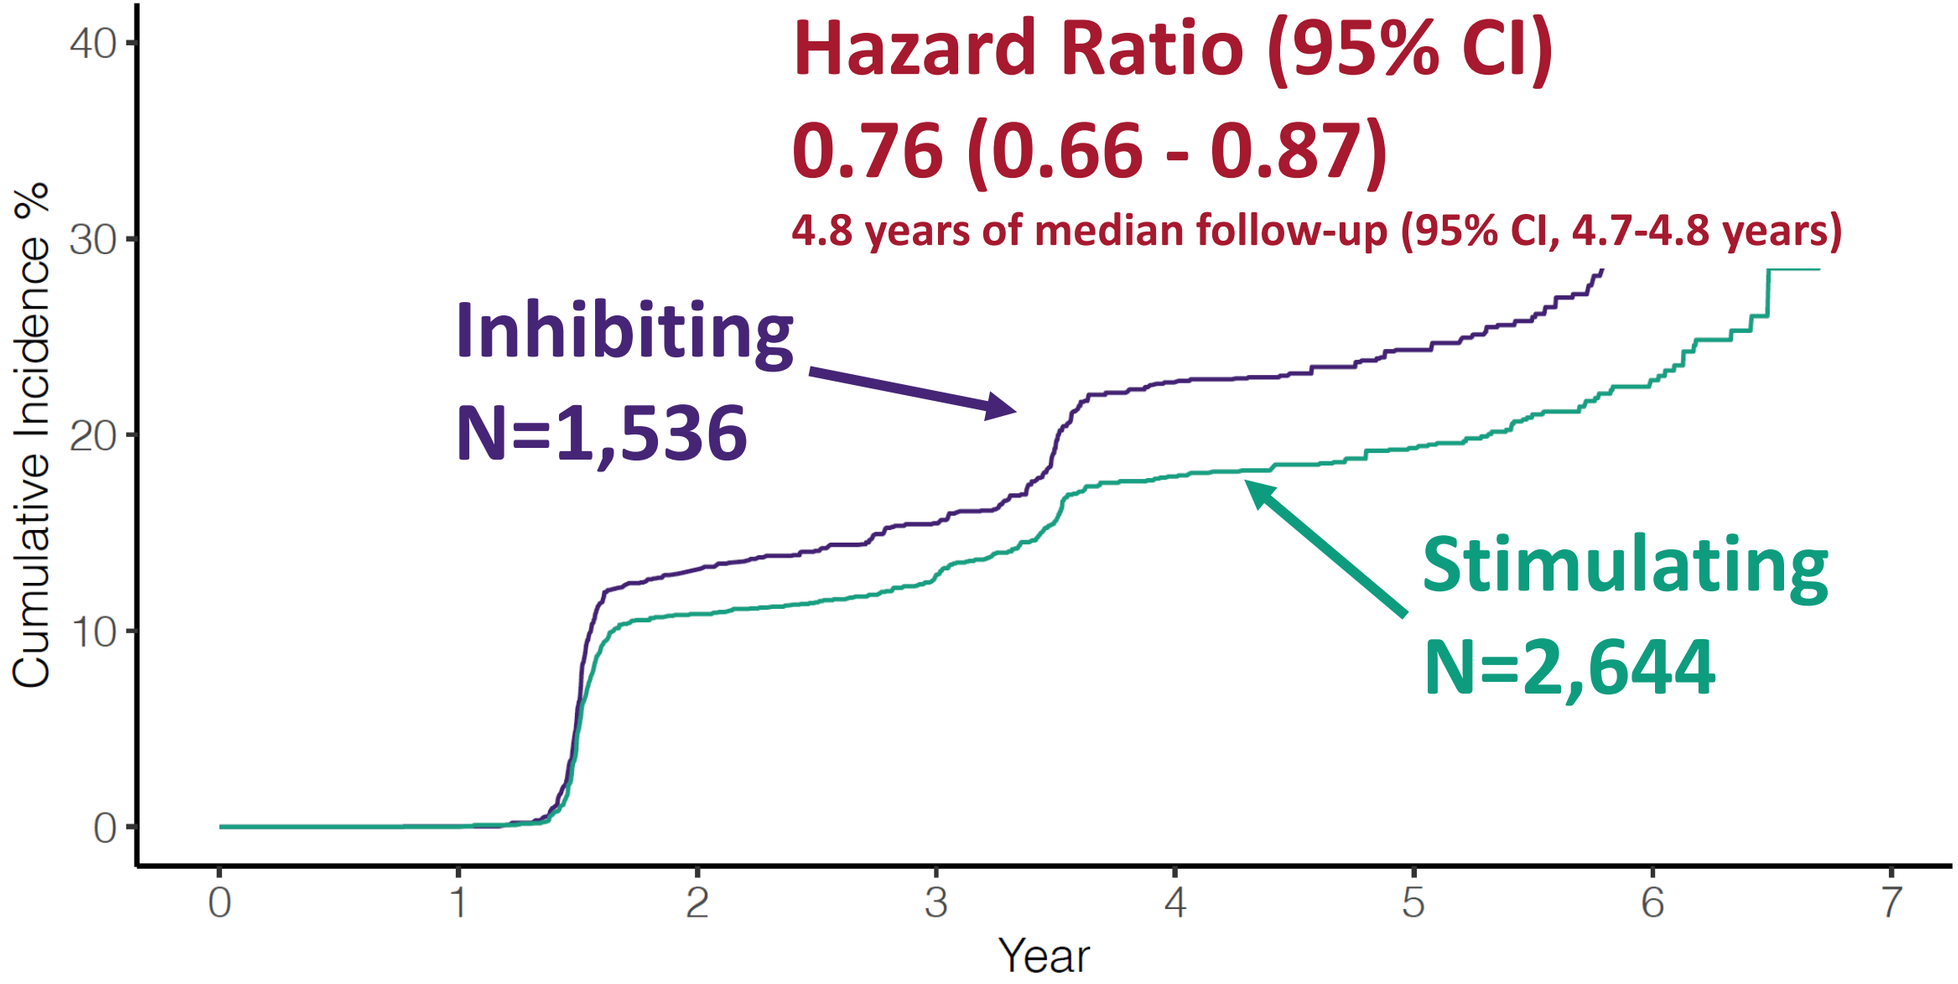
In an active-comparator, new-user design, we emulated a target trial to evaluate the effect of initiating an ARB (N=727) vs. ACEI (N=1,313) on MCI of dementia using SPRINT MIND



4.9 years median follow-up

Comparing the incidence of dementia or MCI among users of regimens that contained exclusively stimulating vs inhibiting antihypertensives

Secondary analysis of SPRINT MIND, cohort study comparing prevalent users of regimens containing exclusively stimulating vs inhibiting antihypertensives at the 6-month study visit.



Implications

- We ***did not*** find evidence of an appreciable effect of initiation of an ARB- vs. ACEI-based medication regimen on MCI or probable dementia in SPRINT MIND.

- ***We did find evidence*** of lower risk of MCI or probable dementia among new users of an ARB vs. ACEI in ***the standard treatment arm***, suggesting benefits of intensive BP control may have diminished any potential beneficial effects of ARBs over ACEIs.

- Prevalent users of regimens that contain exclusively **antihypertensives that stimulate** vs inhibit type 2 and 4 angiotensin II receptors **had lower rates of incident cognitive impairment.**

Implications

- The US prevalence of hypertension is large (~45%)
- CVD and ADRD prevalence will rise substantially with the aging US population
  - The potential for public health benefit of optimizing anti-HTN medication use to prevent CVD and ADRD is enormous.
- ~33 million US adults are currently taking RAS blockade
- ~20 million are on an ACEI
- Even a 10% relative benefit of ARBs could provide an enormous population health impact of switching first-line RAS-blockade from ACEIs to ARBs

NATIONAL ACADEMY OF MEDICINE

DISCUSSION PAPER

Can Preferentially Prescribing Angiotensin II Receptor Blockers (ARBs) over Angiotensin-Converting Enzyme Inhibitors (ACEIs) Decrease Dementia Risk and Improve Brain Health Equity?

Introduction

Part I: ARBs vs. ACEIs

Background

Methods

Results

Conclusions

Part II: Therapeutic Inertia

Background

Methods

Results

Conclusions

Summary

1. ARBs and ACEIs have similar efficacy in terms of blood pressure-lowering and CVD event reduction
2. ARBs have a more favorable safety profile than ACEIs
3. Short-term RCT data suggest a comparative benefit of ARBs over ACEIs in preventing cognitive decline
4. There is biological plausibility of a cognitive benefit of ARBs over ACEIs
5. There is growing data from secondary data analyses suggesting a comparative benefit of ARBs over ACEIs
6. There is currently no effective disease-modifying treatment for dementia

Summary

- SPRINT was designed to achieve an SBP goal of 135 to 139 mm Hg in the standard arm.
- However, intensification only indicated in the standard group if:
  - SBP >140 mm Hg at 2 consecutive study visits or
  - SBP >160 mm Hg at a single visit
- To address, we performed 2 sensitivity analyses:
  1. Redefining therapeutic inertia to require 2 consecutive study visits where SBP was above goal with no change or a reduction in the participant's antihypertensive medication regimen intensity for both randomized treatment groups.
  2. Restrict to the standard group and required either 1 study visit with SBP ≥160 mm Hg or 2 consecutive study visits with SBP ≥140 mm Hg.

Model 1 ***N=4,415†***	1 (Reference)	0.94 (0.90, 1.00)	0.86 (0.76, 0.95)
Model 2 ***N=4,364†***	1 (Reference)	0.96 (0.90, 1.02)	0.87 (0.78, 0.97)
Model 3 ***N=4,377†***	1 (Reference)	0.94 (0.88, 1.01)	0.89 (0.79, 1.00)
Model 4 ***N=4377†***	1 (Reference)	0.99 (0.92,1.05)	0.99 (0.87,1.10)
Model 5 * ***N=4,377†***	1 (Reference)	0.99 (0.92,1.05)	0.95 (0.84,1.06)

Model 1 included race/ethnicity and time as the only fixed effects.
Model 2 was adjusted for race and time, in addition to age, sex, education, employment, living with others, insurance status, source of care, smoking status, BMI, depression, statin use, aspirin use, as well as baseline SBP, eGFR, serum potassium, serum sodium, number of antihypertensive medications, prior mTIS, ACEI/ARB, CCB, thiazide diuretic, loop diuretic, beta-blocker, alpha-blocker, and number of non-antihypertensive medications.
Model 3 added clinical measurements and serious adverse events reported within one month prior of the study visit.
Model 4 added mm Hg the SBP is above the treatment goal and the number of prior study visits with therapeutic inertia.
Model 5 added an interaction between race/ethnicity and time.

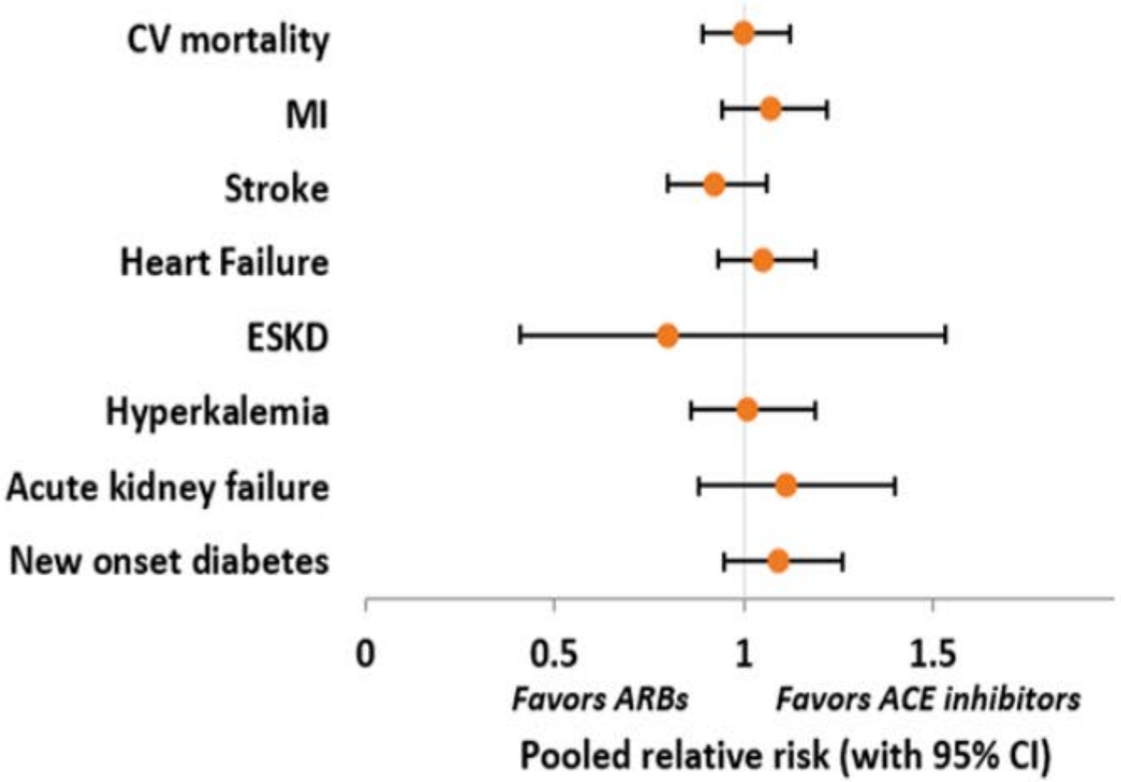
ANGIOTENSIN II RECEPTORS, THEIR FUNCTIONS AND LOCATION

Drug (Active Metabolite)	AT_1 Receptor Affinity, nmol/L	Bioavailability, %	Food Effect	Active Metabolite	Half-Life, h	Protein Binding, %	Dosage, mg/d
Losartan (EXP 3174)	IC_{50}, 20	33	No	Yes	2 (6–9)	98.7 (99.8)	50–100
Valsartan	IC_{50}, 2.7	25	Yes, −40%	No	9	95	80–320
Irbesartan	IC_{50}, 1.3	70	No	No	11–15	90*	150–300
Candesartan cilexetil							
(TCV 116)	. . .	. . .	No	Yes	3.5–4	. . .	4–16 (32)
(CV11974)	K_i, 0.6	42			3–11	99.5	
Telmisartan	K_i, 3.7	43	No	No	24	>99	40–80
Eprosartan	IC_{50}, 1.4–3.9	15	No†	No	5–7	98	400–800

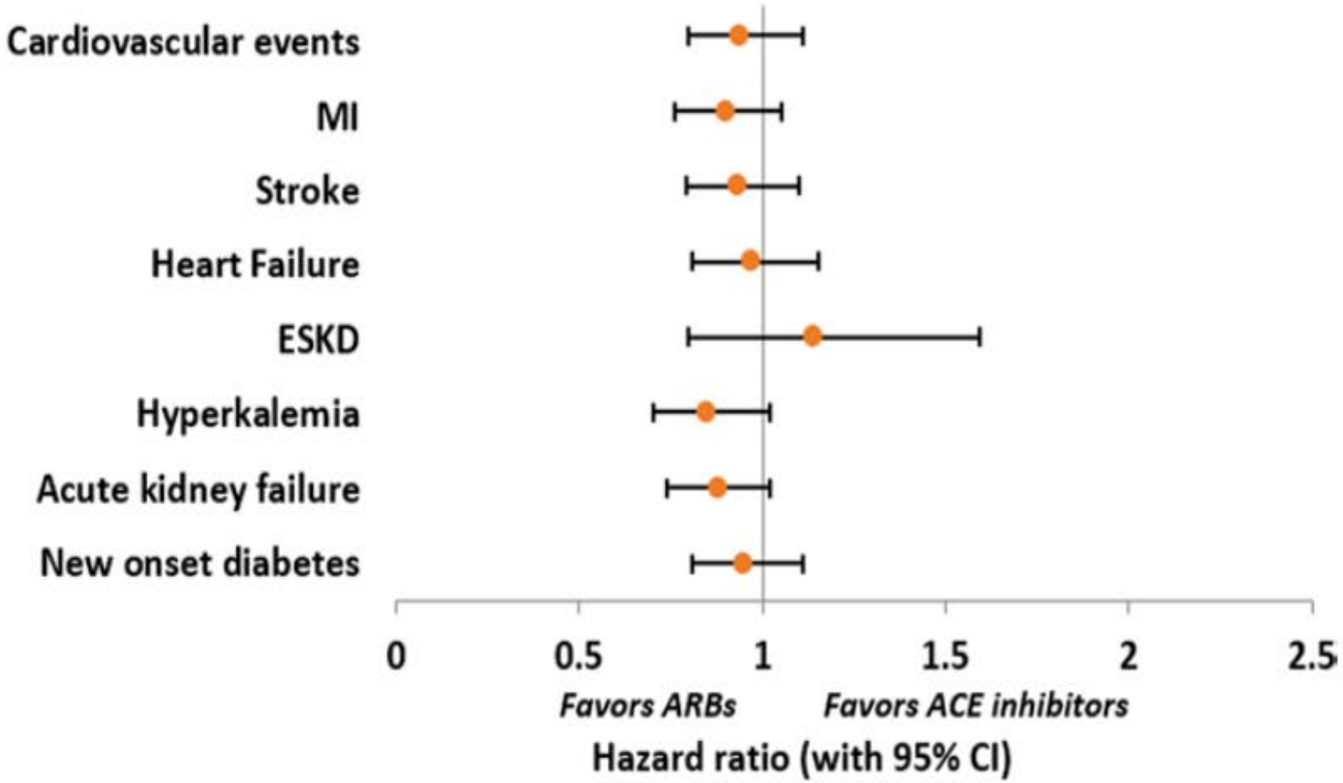
Values are mean or range. K_i indicates inhibition constant.
*Some studies suggest that irbesartan has a greater protein binding (>95%).
†Depending on the formulation, there may be a food effect.

PK DIFFERENCES BETWEEN INDIVIDUAL ARBS

Meta-analysis by Bangalore et al. on head-to-head trials (7 trials)



Multinational cohort study by Chen et al. (>3 million patients)



META-ANALYSIS OF RCTS- COMPARATIVE EFFECTS OF ARBS VS ACEIS ON CVD OUTCOMES

Treatment \ Comparison group	Placebo	CCBs	ACE inhibitors	β-blockers	Diuretics
ARBs	0.60 ± 0.18 ($P = 0.02$)	0.57 ± 0.24 ($P = 0.06$)	0.47 ± 0.17 ($P = 0.04$)	0.67 ± 0.18 ($P = 0.01$)	0.54 ± 0.19 ($P = 0.04$)
CCBs	0.02 ± 0.19 ($P = 0.91$)	–	–0.11 ± 0.22 ($P = 0.65$)	0.10 ± 0.17 ($P = 0.58$)	–0.03 ± 0.24 ($P = 0.89$)
ACE inhibitors	0.13 ± 0.17 ($P = 0.49$)		–	0.21 ± 0.15 ($P = 0.23$)	0.07 ± 0.17 ($P = 0.70$)

Conclusions

Part II: PATH and HTEs

Background

Methods

Results

Conclusions

Summary

1. To identify possible cases of dementia a brief Cognition Screening Battery will be administered to all participants.
2. Participants who score below the pre-designated screening cut-point for possible cognitive impairment were administered a more comprehensive and detailed neurocognitive test battery (the Extended Cognitive Assessment Battery) plus the Functional Assessment Questionnaire (FAQ) which assesses impairments in daily living skills as a result of cognitive impairments.
3. All the above available tests and questionnaire data were submitted to a centralized, web-based system for adjudication by a panel of dementia experts who will assign final study classifications of probable dementia, MCI or no impairment (NI).

The Hear and Know: Hearing Loss, Cognition, and Cochlear Implants in Older Adults

HEALTH
UNIVERSITY OF UTAH

Thoughts by
Richard K. Gurgel, MD, MSCI
Associate Professor – Otolaryngology

DISCLOSURES

- Research funding:

Dementia prevention, intervention, and care

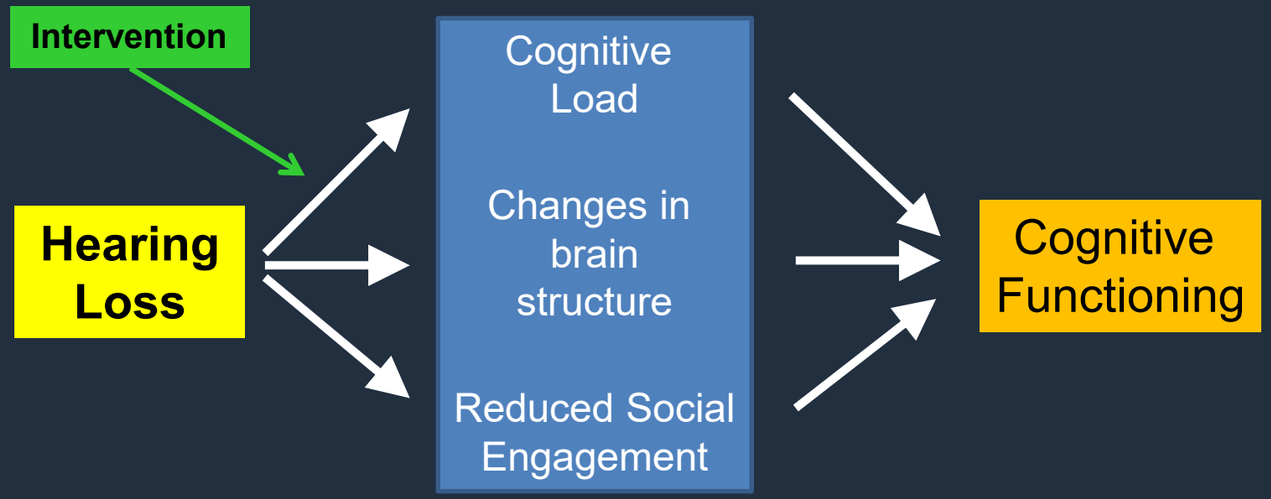
Gill Livingston, Andrew Sommerlad, Vasiliki Orgeta, Sergi G Costafreda, Jonathan Huntley, David Ames, Clive Ballard, Sube Banerjee, Alistair Burns, Jiska Cohen-Mansfield, Claudia Cooper, Nick Fox, Laura N Gitlin, Robert Howard, Helen C Kales, Eric B Larson, Karen Ritchie, Kenneth Rockwood, Elizabeth L Sampson, Quincy Samus, Lon S Schneider, Geir Selbæk, Linda Teri, Naaheed Mukadam

9% of modifiable risk of Alzheimers disease attributed to hearing loss

G. LIVINGSTON ET AL., LANCET, 19 JULY 2017

Hearing Loss & Cognition

Hearing Loss as a Modifiable Risk Factor

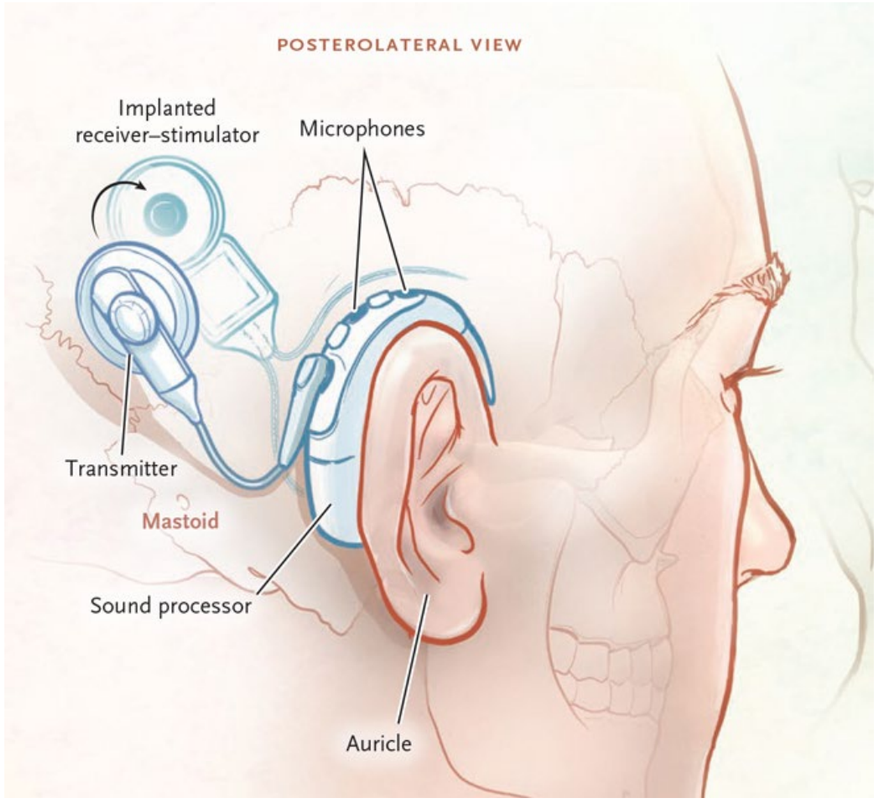


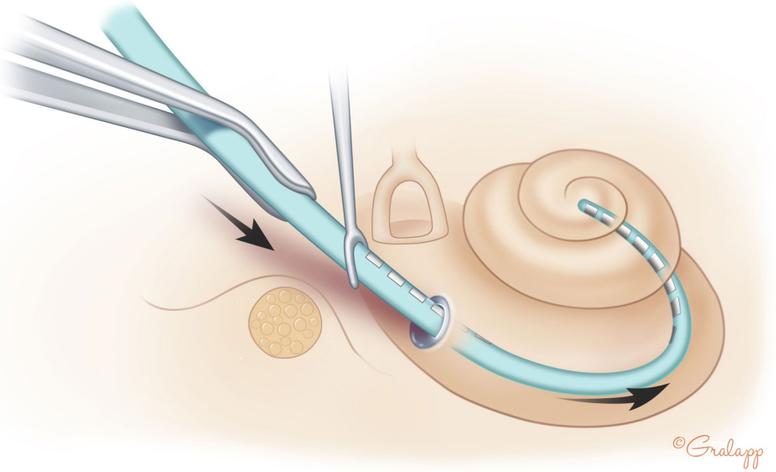
Hearing loss intervention could:

- Reduce the cognitive load of processing degraded sound
- Provide increased brain stimulation
- Improve social engagement

Role of HL as a potentially modifiable, mid & late-life risk factor for cognitive decline & dementia

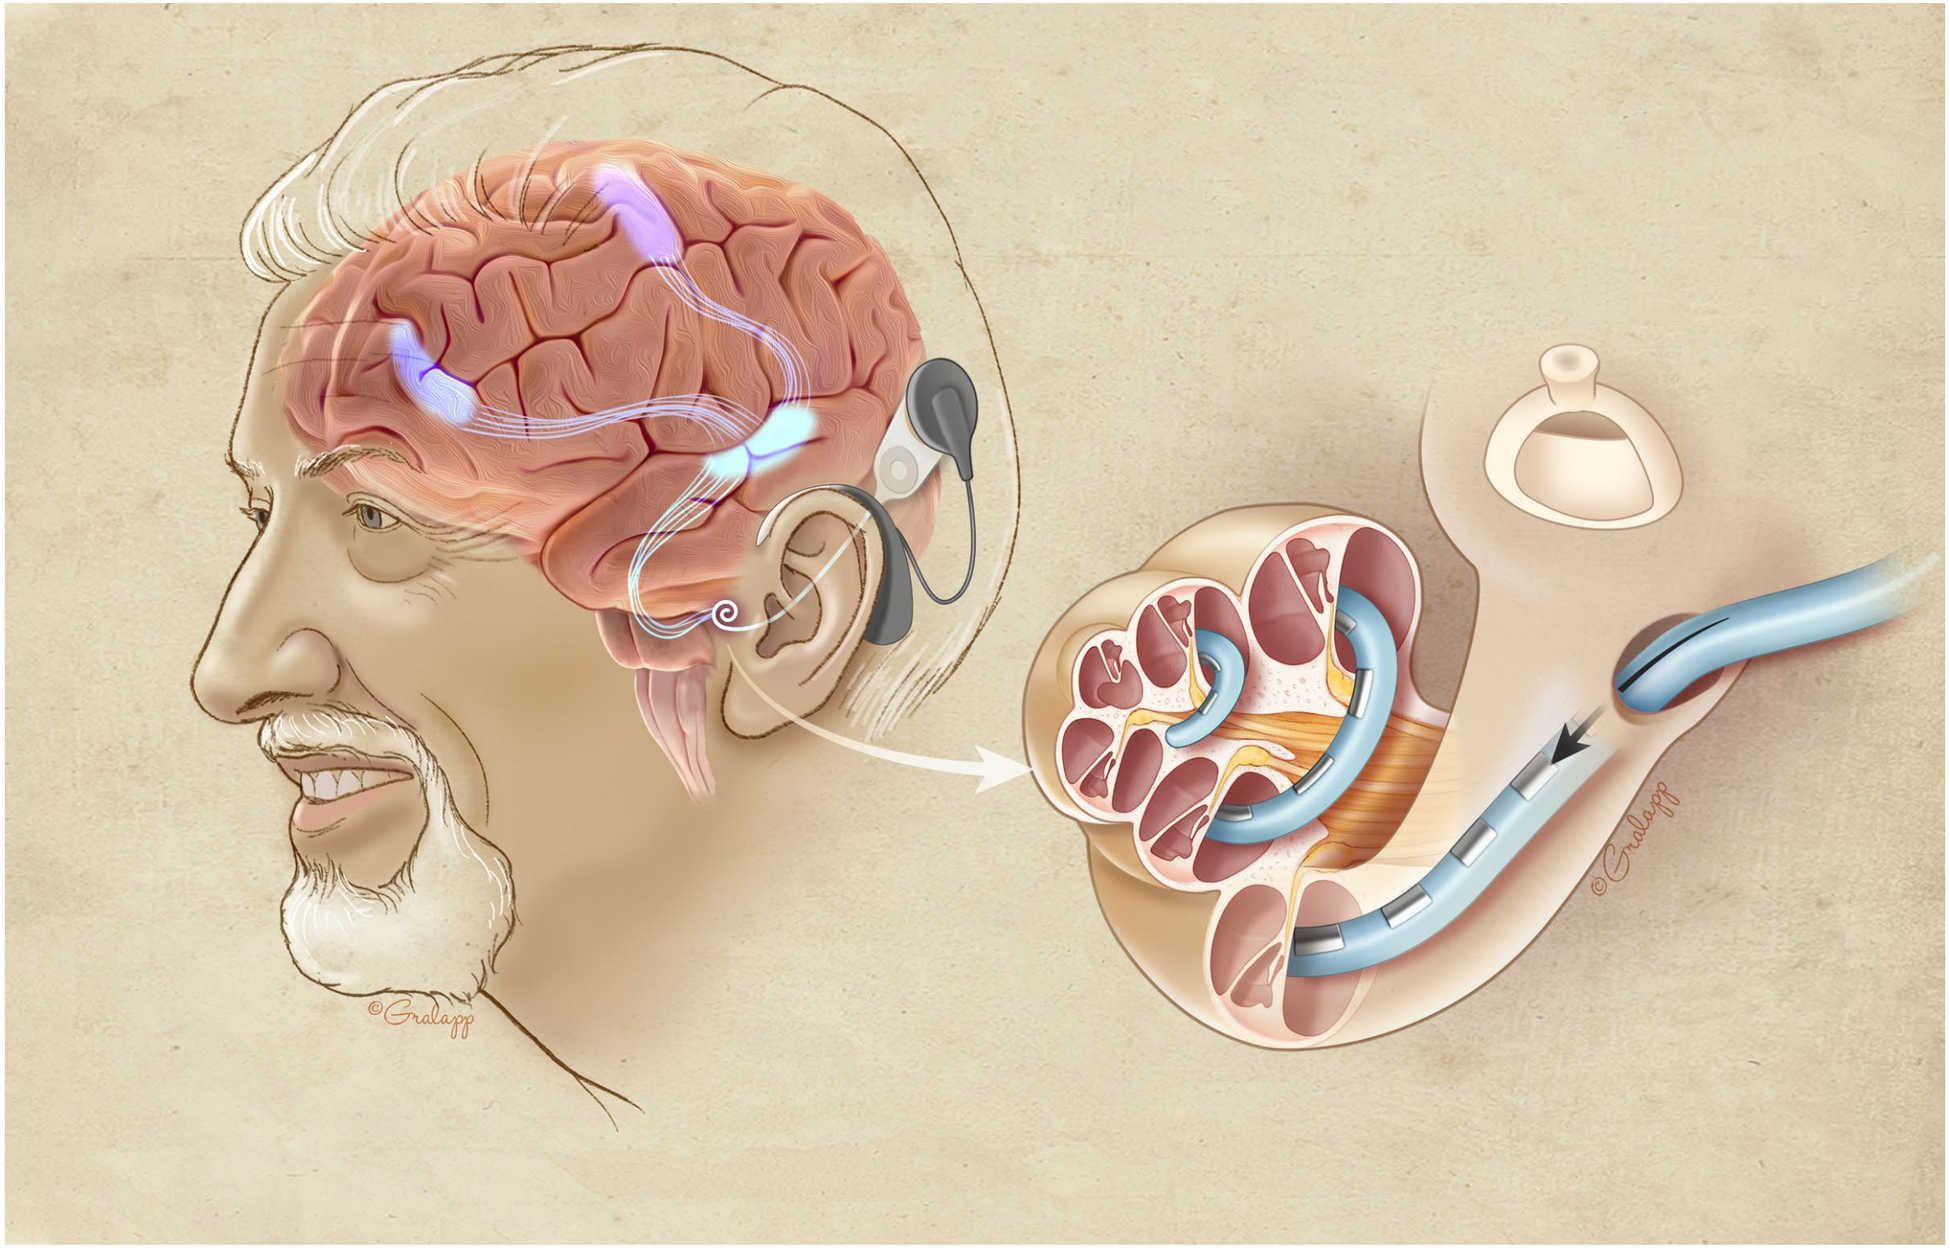
COCHLEAR IMPLANTS





COCHLEAR IMPLANTS IN OLDER ADULTS

- Only 5-10% of adult cochlear implant candidates in the US have received cochlear implants
- Average delay from time of profound ARHL to CI is 10 years
- Fastest growing segment of CI users = older adults



COCHLEAR IMPLANT COGNITION

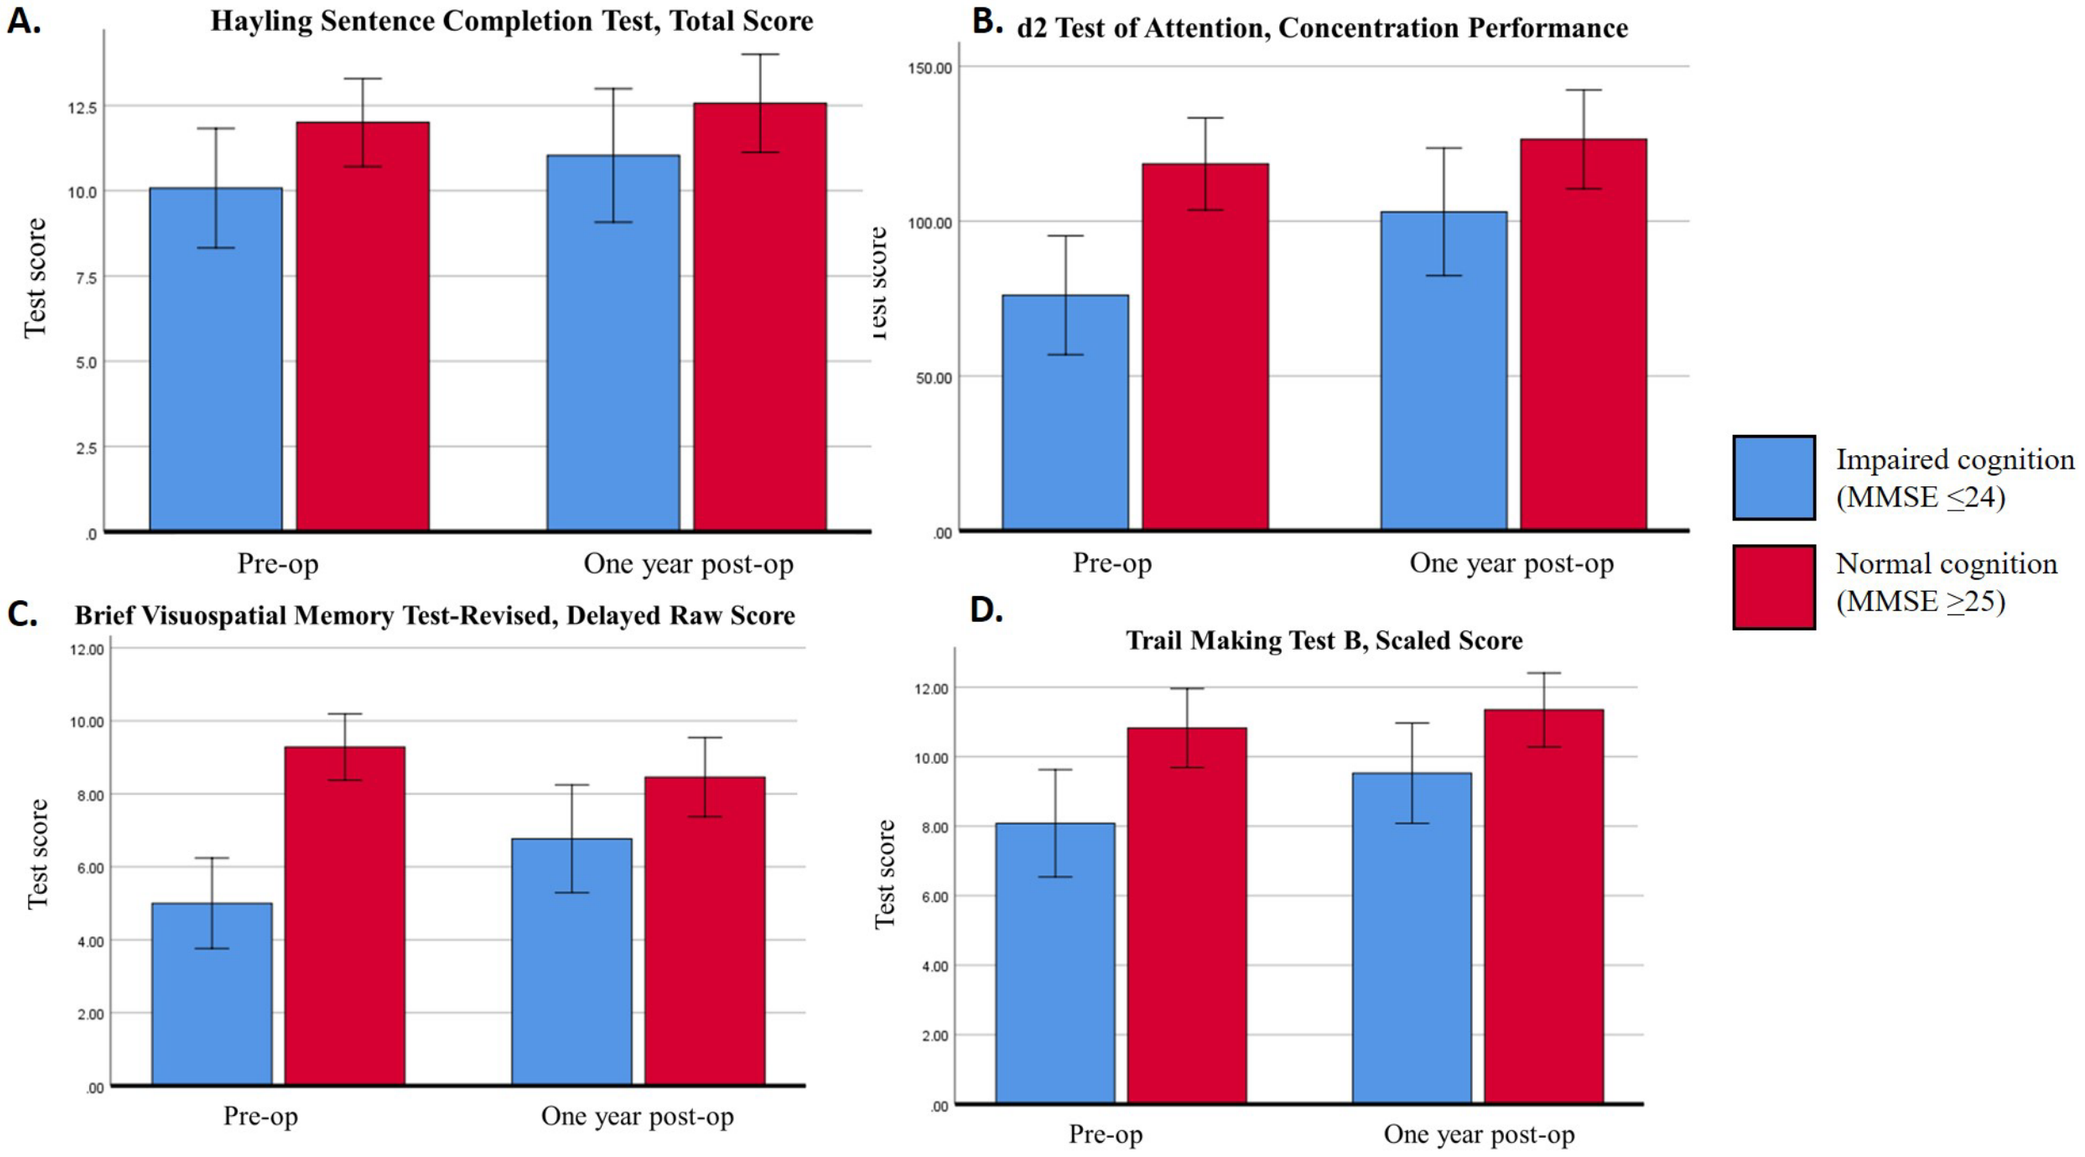
The Laryngoscope

Evaluating the Impact of Cochlear Implantation on Cognitive Function in Older Adults

Richard K. Gurgel, MD, MSCI; Kevin Duff, PhD; Norman L. Foster, MD; Kaitlynn A. Urano, AuD; Alvin deTorres, MD

- 37 patients, ≥65 yo
- Cognitive testing before and 1 year after cochlear implant

Cognitive domain	Verbal stimuli/responses	Visual stimuli/responses
Simple attention	Digit Span	Spatial Span
Sustained attention	Stroop Color Word Test	d2 Test of Attention
Learning and memory	HVLT-R	BVMT-R
Executive functioning	Hayling Sentence Completion Test	Trail Making Test Part B



COCHLEAR IMPLANTS COGNITION

- Cochlear implants improve cognition in older adults
- Individuals with cognitive impairment - Even more improvement
- Do cochlear implants protect against dementia?

CONCLUSIONS

- There is an association between hearing loss and dementia
- Cochlear implants are safe and effective in older adults, and can improve cognition
- Cochlear implants may reduce risk of dementia

Sensory Integration for Navigation:
Effects of Age and Sensory Impairment

Sarah Creem-Regehr
Department of Psychology
University of Utah

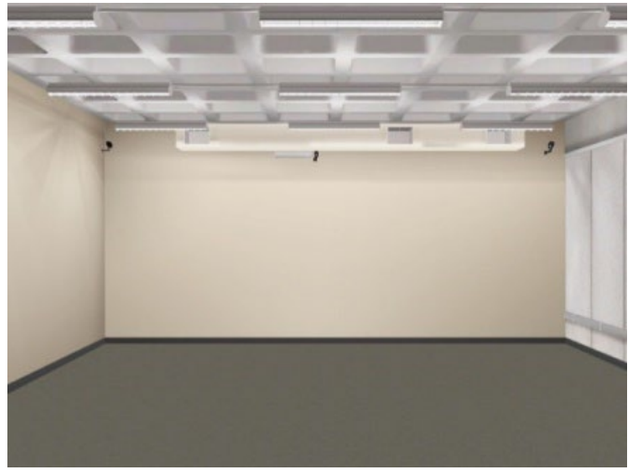
Visual Perception and Spatial Cognition
THE UNIVERSITY OF UTAH
http://www.cs.utah.edu/research/groups/percept/

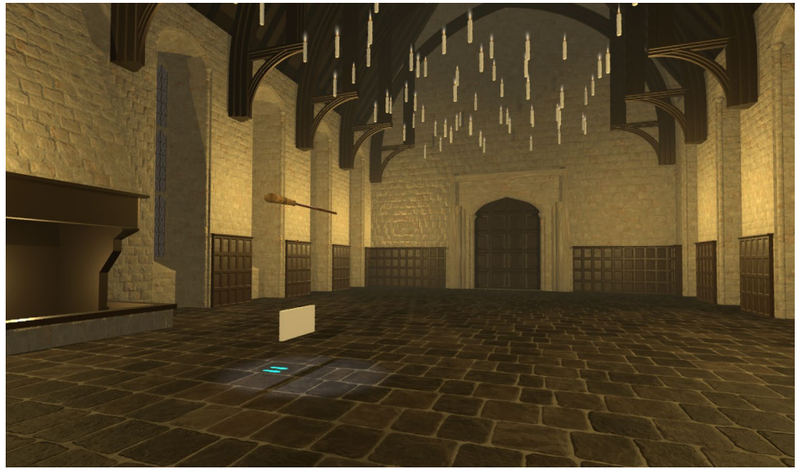
Visual Perception and Spatial Cognition Lab

We study how people perceive, learn, and navigate spaces in natural, virtual, and visually impoverished environments.

Basic research motivated by real world problems

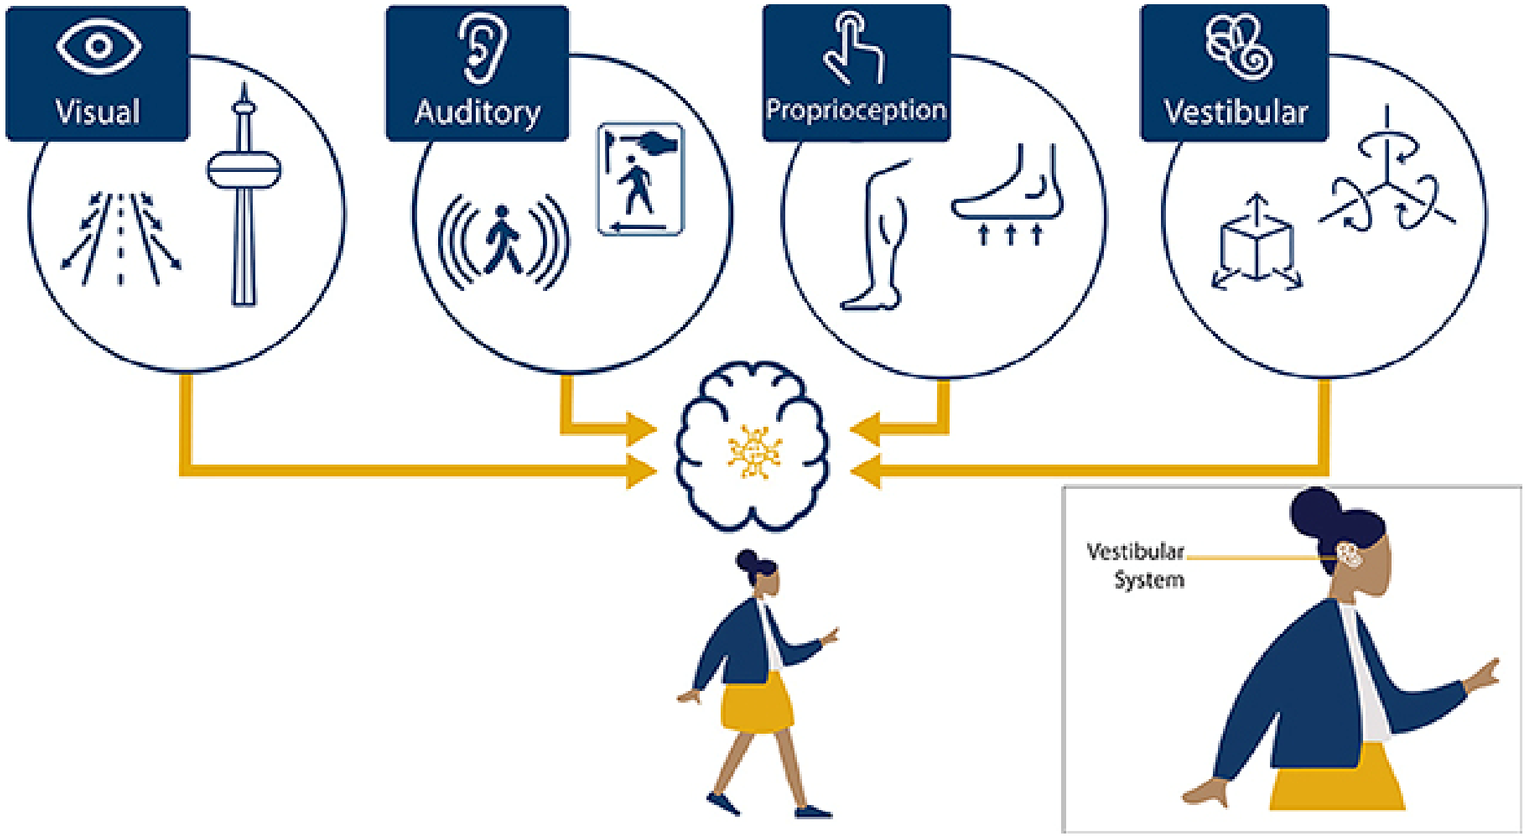
- Perceptual fidelity of virtual environments
- Navigation challenges with healthy aging and sensory pathology





Navigation and Aging

Navigation ability is critical for independent living and influenced by age-related changes in sensory processing

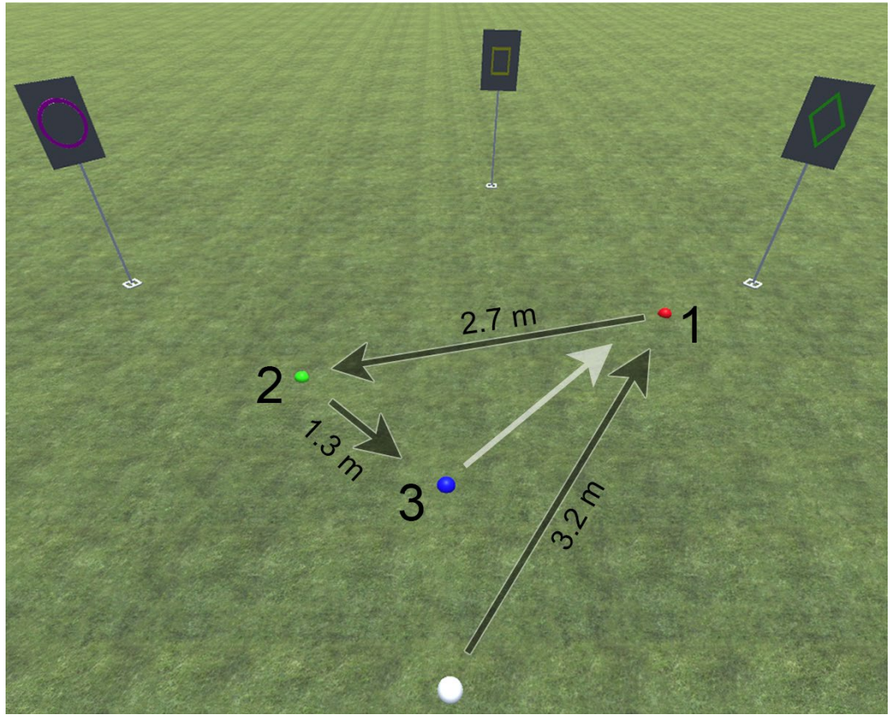


Campos et al, 2020
Frontiers for Young Minds

Navigation and Aging

How are visual and self-motion cues integrated for balance and navigation? (CoA pilot grant with P. Fino and J. Stefanucci)

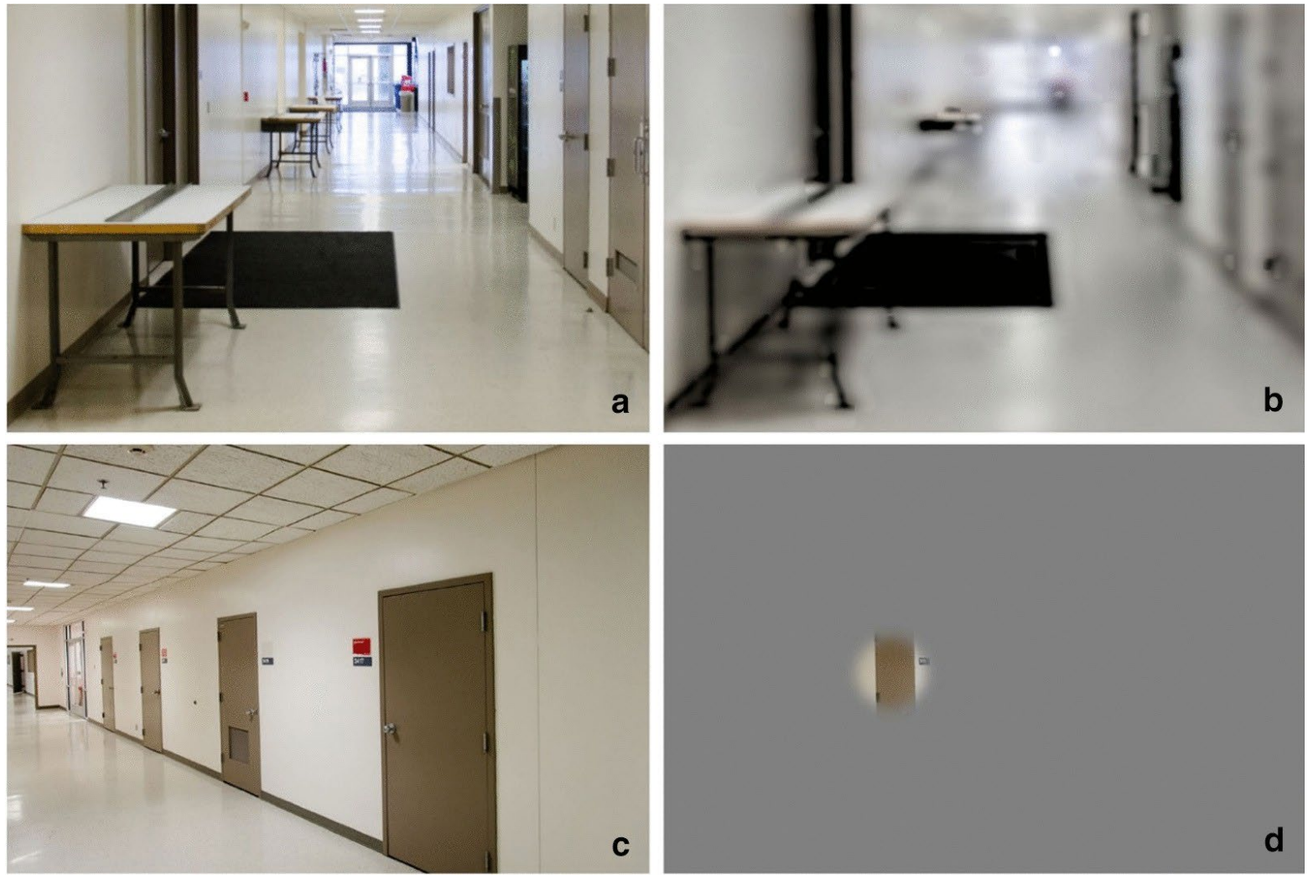
- Do younger and well-aging older adults use the same sensory weighting strategies?
- How does sensory weighting for balance relate to navigation?
- Is sensory weighting similar in real and virtual environments?



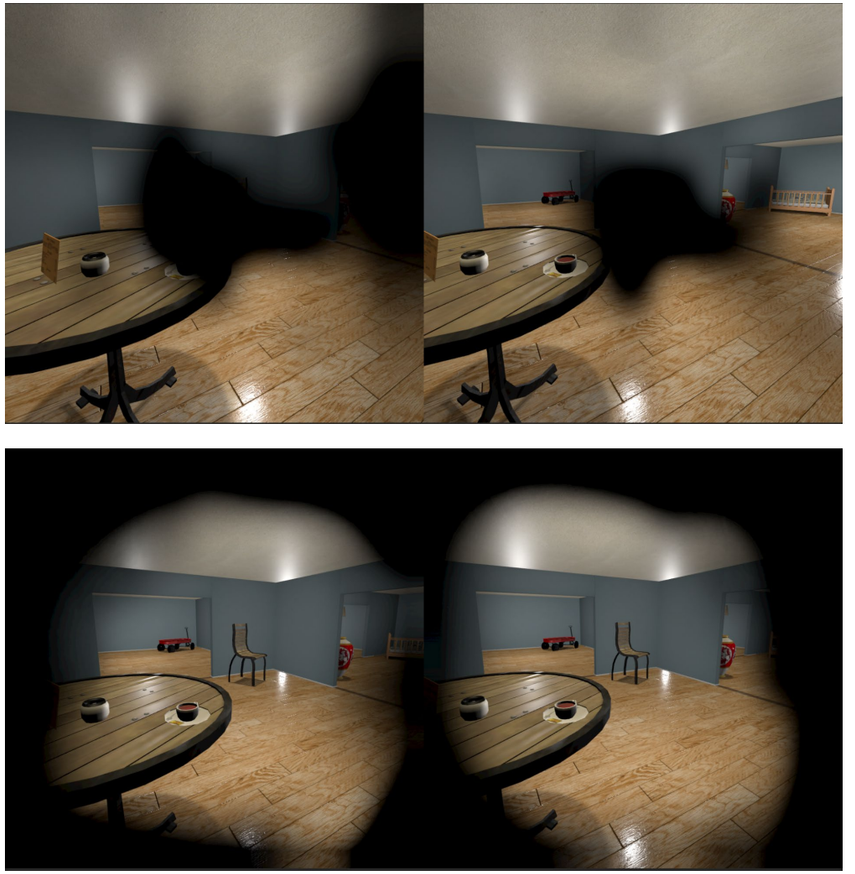
Homing Task in Virtual Reality

Navigation and Sensory Impairment

How does severe vision loss (low vision) influence sensory integration for navigation?



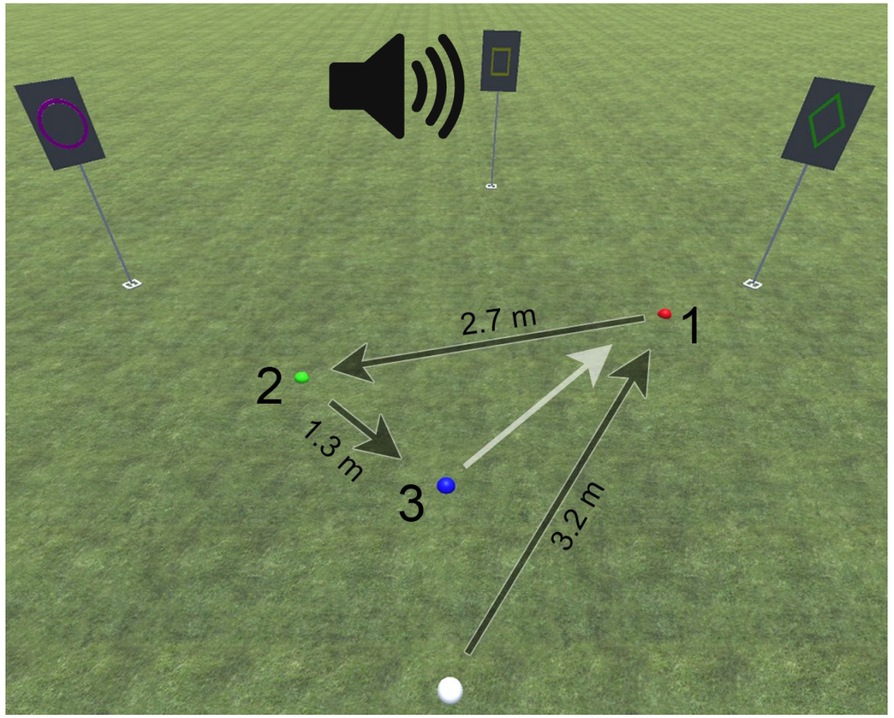
VR Low Vision Simulation



Navigation and Sensory Impairment

How are <u>auditory</u> cues integrated with vision and self-motion to influence balance and navigation? (American Otological Society grant to Corey Shayman, MD-PhD student)

- In well-aging individuals
- In simulated vision or vestibular loss



Homing Task in Virtual Reality

Cognitive Resilience and Collaborations

Development of virtual reality methods for use in research and clinical applications

- Controlled simulations
- Accessible and interesting to participants

Understanding sensory weighting to improve rehabilitation, training, and assistive devices

Shared interests in core resources of proposed Pepper Center

- Clinical Core: expanded and longitudinal participant database including cognitive and functional status

Motor Behavioral Profile Scores as Biomarkers for Alzheimer's Disease

Muscle Strength	Motor Speed	Fine Motor Skill	Coordination	Gait	Balance	Motor Learning	Drawing

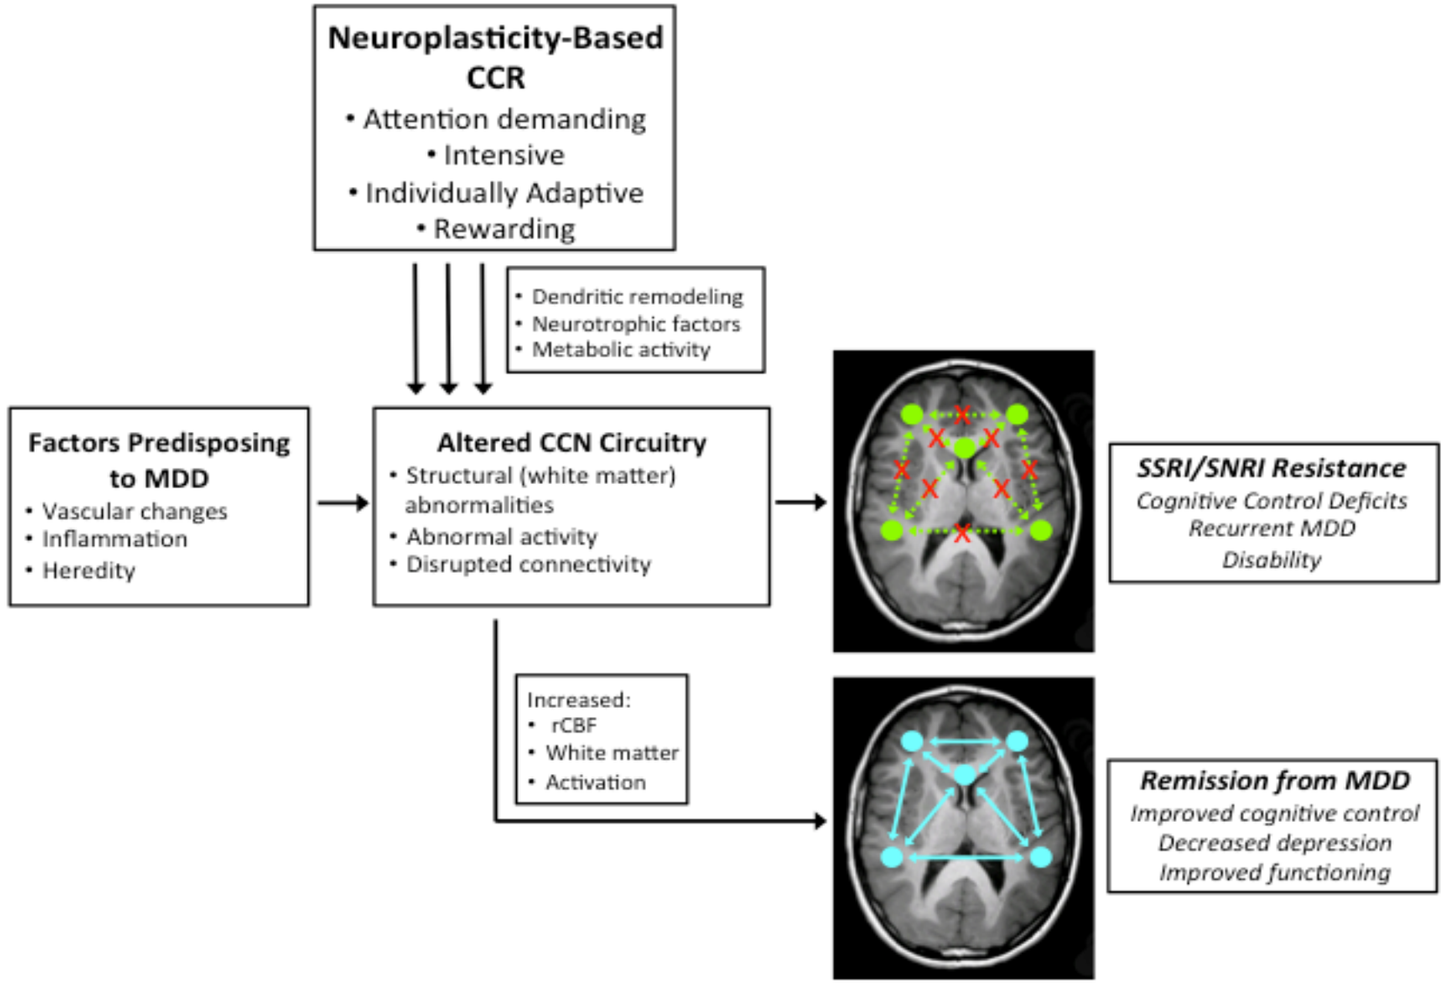
HEALTH
UNIVERSITY OF UTAH

NEUROBIOLOGICAL MODEL OF NEUROFLEX: GRAPHICAL ABSTRACT



PRINCIPLES OF NEUROFLEX:

PLASTICITY IN AN AGING BRAIN Requires:

- Selection of specific, clinically-relevant network.
- Extensive practice/activation of network
- "Bottom up" + "top down" modules
- ↑ Neurotransmission associated with reward (Bao et al, 2001; Mahncke et al; 2006)

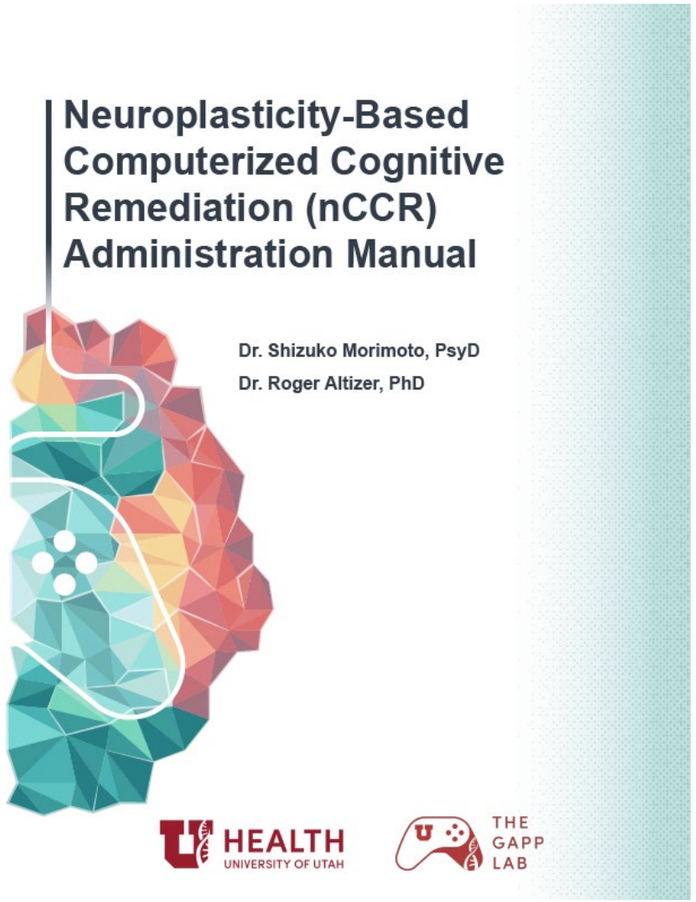
PARADIGMS ENGAGE CCN WITH SENSORY, MOTOR, AND COGNITIVE TASKS THAT ARE:

- Increasingly challenging
- Dynamic difficulty adjusted
- "Layered"
- Attention demanding
- Immediately rewarding (Bao et al, 2001; Bao et al, 2004;Mahncke et al; 2006)

NEUROFLEX IS A **DIGITAL SOLUTION** DEVELOPED TO TREAT THE SPECIFIC **COGNITIVE DEFICITS** THAT PREDICT POOR CLINICAL OUTCOMES IN DEPRESSION.

IT IS:

- Short (4 weeks)
- Efficacious For Mood *and* Cognition
- Easily Disseminated
- Cost Effective



- NeuroFlex is Designed To Be a

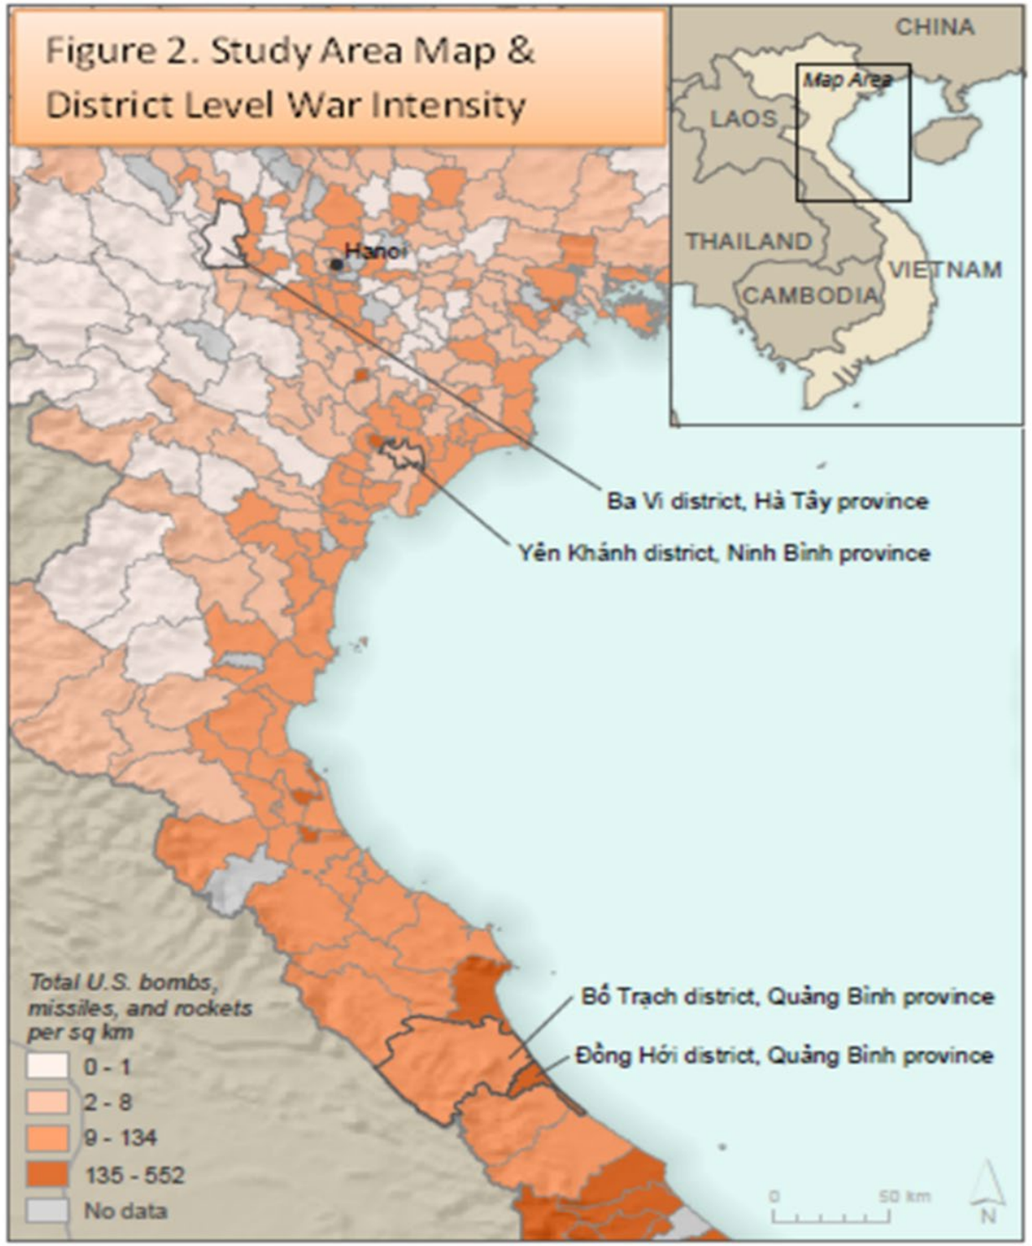
Cognitive Function & ADRD Risk in the Context of Early Life Wartime Stress Exposures

Kim Korinek, Department of Sociology & The Asia Center, University of Utah

Presentation for Center on Aging Retreat, May 25, 2022

Vietnam Health & Aging Study, 2018 (www.vhas.utah.edu)

- In-person interview & biomarker data collection (N=2,447, age 60+) in northern Viet Nam
  - 'American War' cohort – teens/young adults in 1965-75
  - Multi-stage probability sampling; purposive selection of 4 districts → differential exposure to bombing, wartime stress
  - Wave I (Summer 2018) & Wave II (Summer 2021, 2022); ~12% attrition due to mortality, loss to follow-up
- Omnibus survey; early life & wartime stressors, self-reports of health status, cognitive performance tests (MMSE, CSI-D)
- Biomarker collection (venous blood, hair, anthropometrics) in full sample to assess disease risk; physiological & cognitive aging



The "long arm of war" and cognitive health in low- and middle-income countries (LMICS)

- Alzheimer's Disease (AD) & other neuro disorders, are a global epidemic & substantial share of disease burden in LMICs
- Research on AD's experiential & environmental correlates in LMICs is sparse
- Armed conflict: "environment" of "extreme, violent nature" with clusters of stressors that may accelerate aging[1]
- Benign & adverse life course exposures (e.g., death in family) affect AD risk, in part via "cognitive reserve"[2,3,4]
- Stressed nutritional environments in conflict-affected LMICs underlie deficiencies/illnesses that heighten ADRD[5]

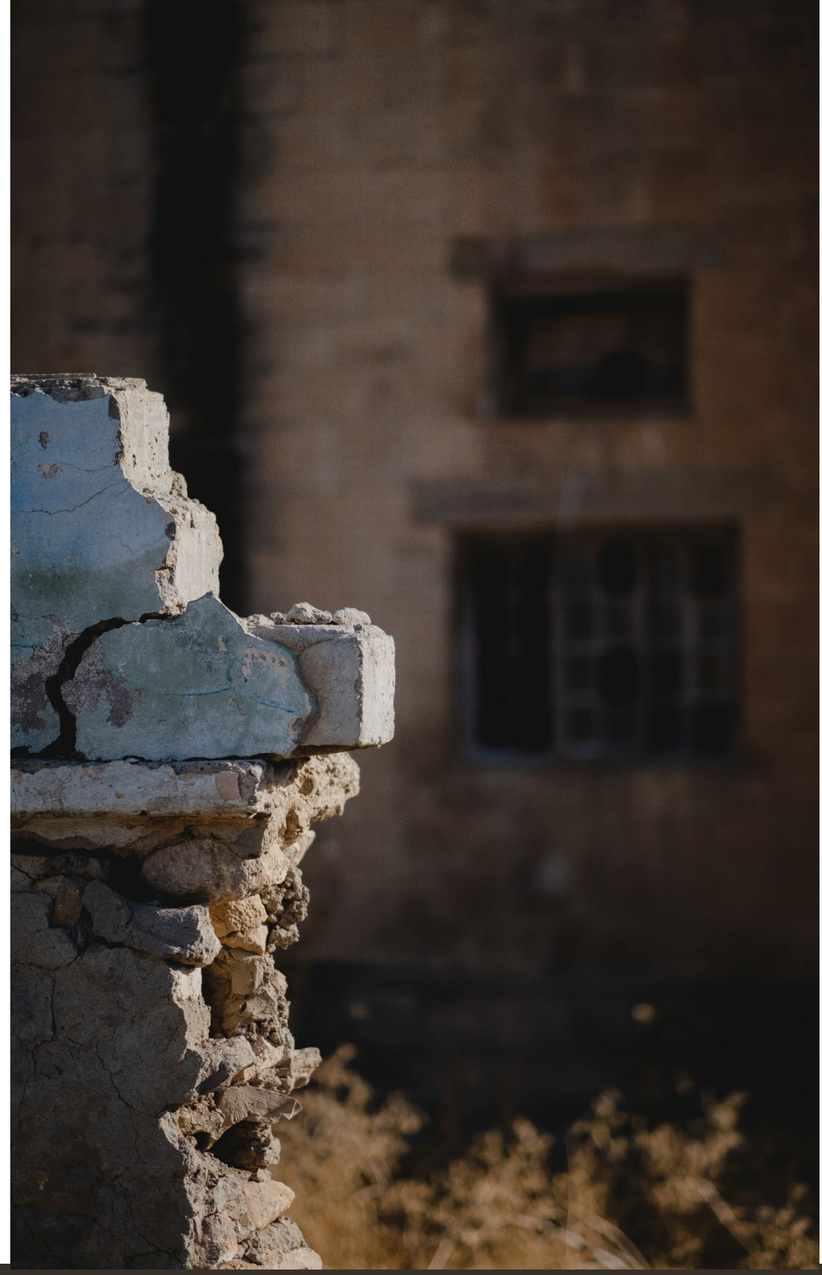


Figure 1. MMSE Cognitive Score by Respondent Age, VHAS 2018

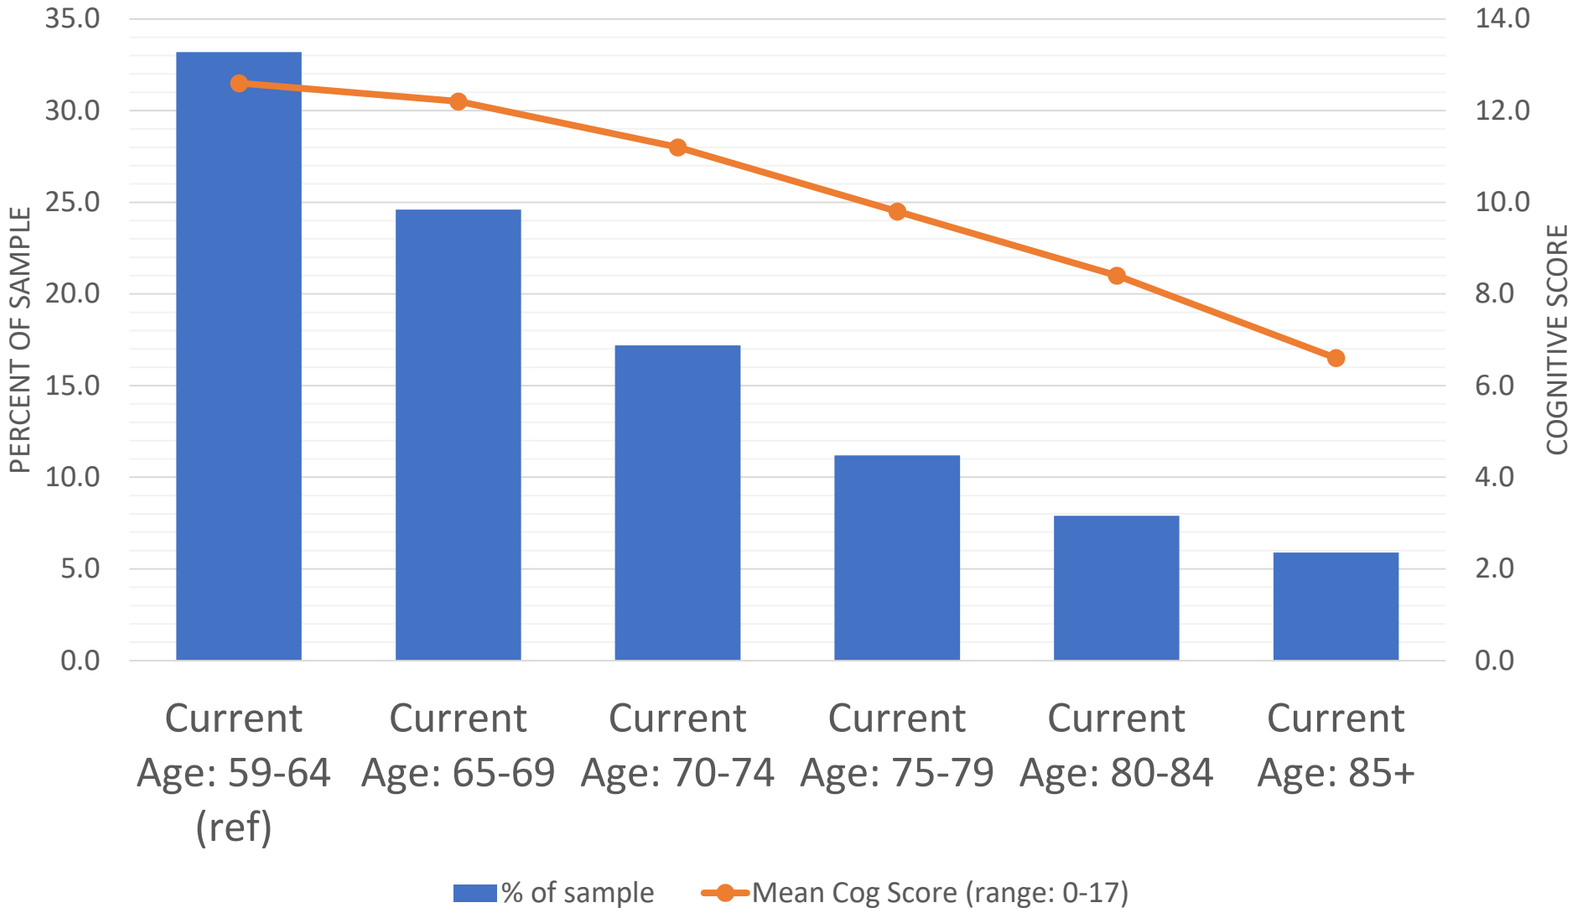

Figure 2. MMSE Cognitive Score by Nutrition/Food Insecurity Covariates, VHAS 2018

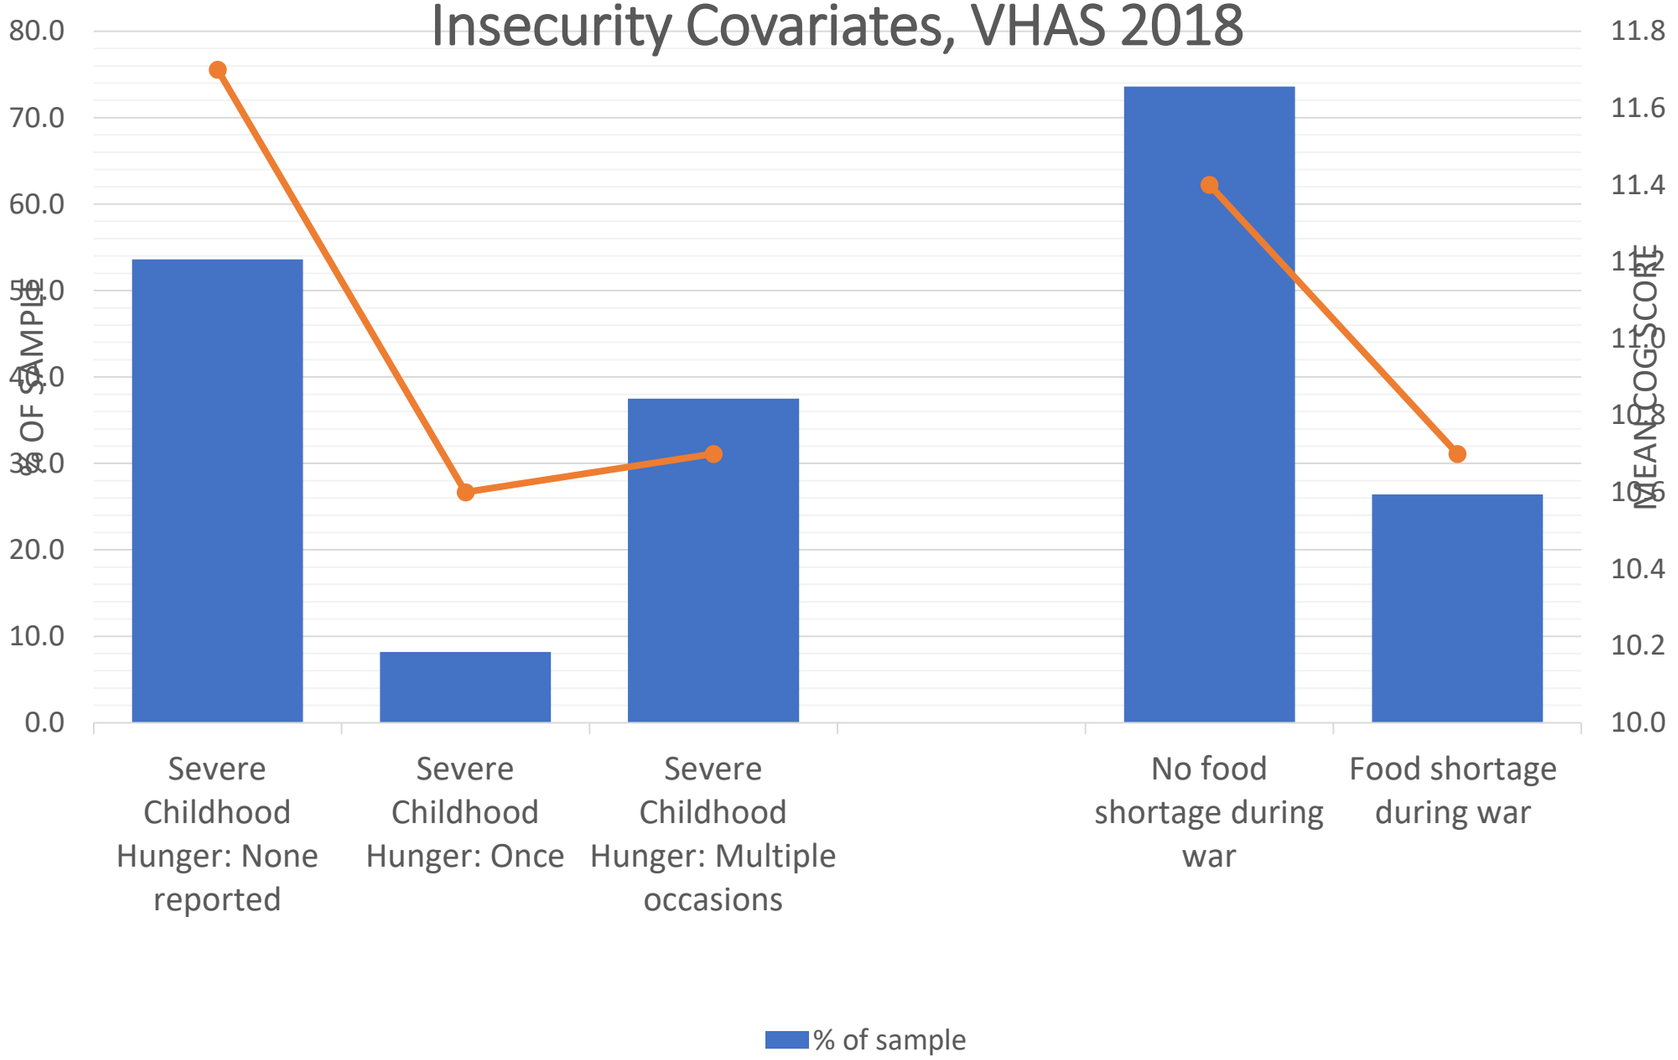

Figure 3. MMSE Cognitive Score by War Stress Exposure Covariates, VHAS 2018

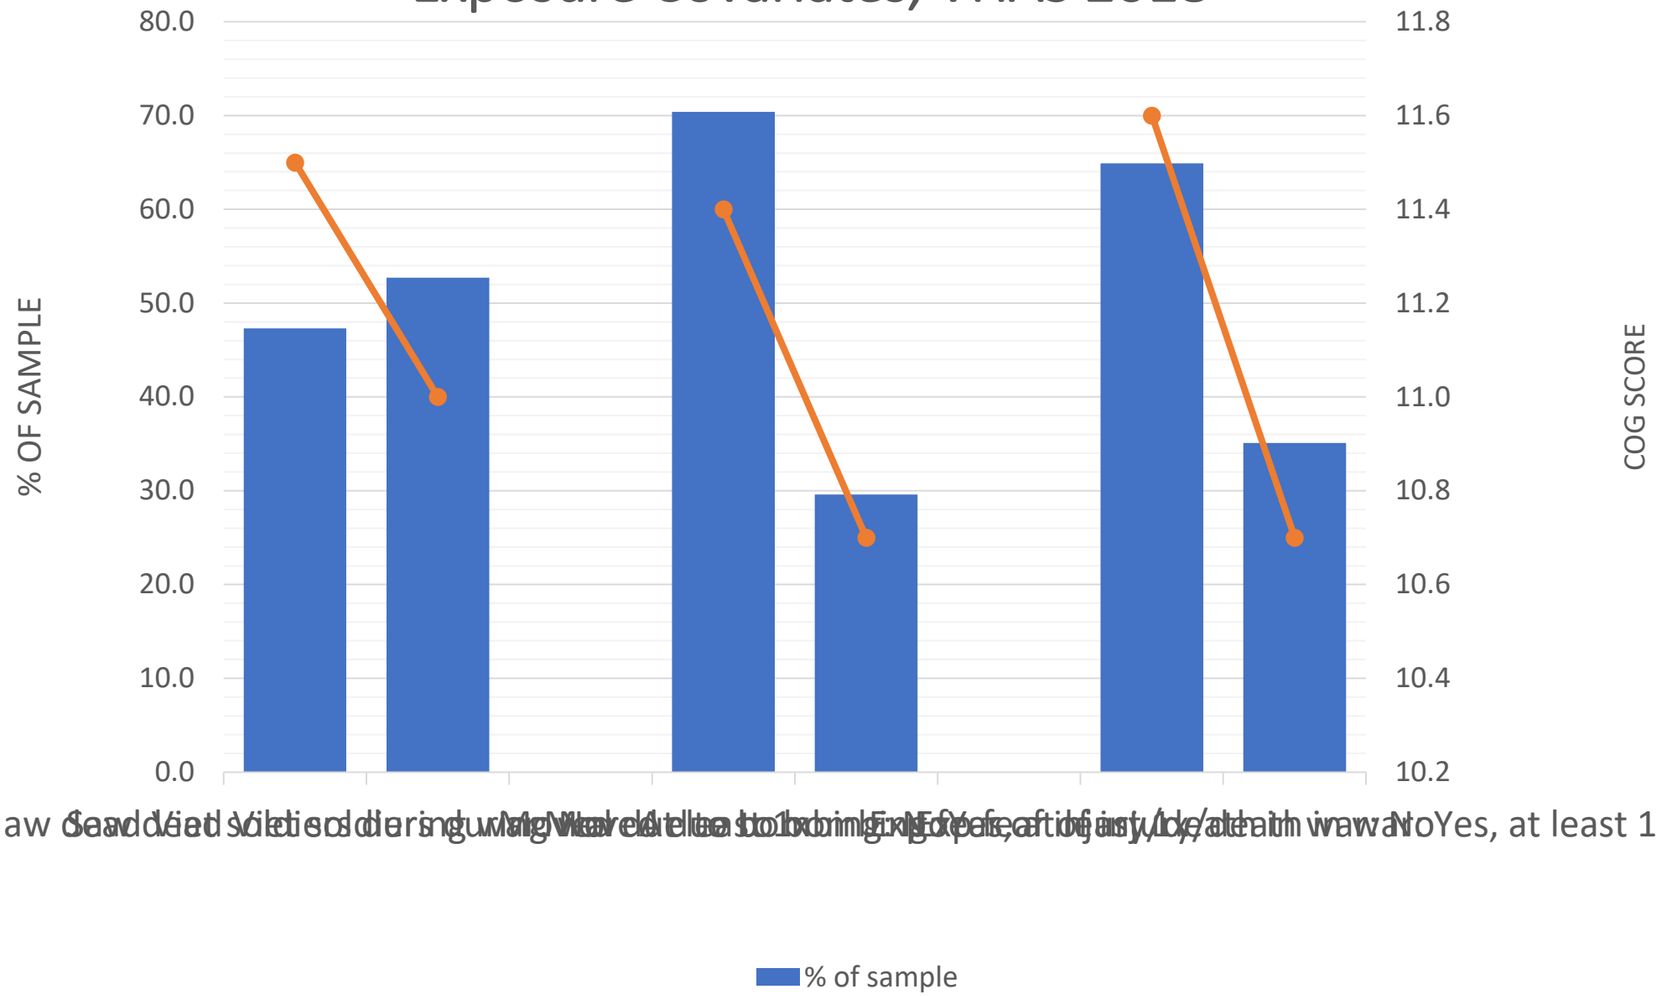

Figure 4. MMSE Cognitive Score by Recent PTSD Symptoms, VHAS 2018

Vietnam Health and Aging Study, NIA ADRD Supplement (2021-22)

Specific Aims:

a) Implement and validate a survey-based cognitive test (Community Screening Instrument for Dementia, CSI-D) to measure cognitive impairment and dementia within a sample of Vietnamese older adults;

b) Develop and test the properties of a modified blood-based biomarker panel for ADRD;

c) While adjusting for established risk factors, analyze associations among early-life war exposures and biological and cognitive performance assessments of ADRD. Focal war exposures include combat and associated forms of violence; environmental adversities including severe food shortage; and contact with Agent Orange.

NIA ADRD Supplement – Proposed Data Collection & Analyses

- **Sample:** Stratified random subsample of VHAS Wave II participants (N=450); strata defined by war-stress exposure severity, gender & military service
- **Implement additional cognitive performance test, CSI-D**
- **Assay blood-based biomarkers for ADRD Risk/Screening**
  - O'Bryant et al. ADRD proteomic biomarker profile[6,7,8]
  - Homocysteine & life course malnutrition/helminths[9,10]
- **Analysis plans:**
  - Validation/replication of O'Bryant et al proteomic profiles & CSI-D
  - Examine life course stress, malnutrition & disease environment correlates of ADRD risk; longitudinal analysis of cognitive decline in context of early life & recent life event stressors

Research Interests

Predicting dementia from health records

Models evaluated with nested cross-validation yielded an AUC of 72% for dementia, 69% sensitivity and 64% specificity.

AUCs higher for AD versus related dementia and using multiple data sources.

	Electronic Health Record Data Source			
	All	Medicare	Inpatient	Outpatient
	Area under the curve (sensitivity, specificity)			
Dementia	0.72 (0.69, 0.64)	0.68 (0.64, 0.62)	0.66 (0.56, 0.64)	0.66 (0.66, 0.59)
Alzheimer's Disease	0.70 (0.62. 0.68)	0.69 (0.64, 0.65)	0.67 (0.61, 0.64)	0.67 (0.59, 0.64)
Related Dementia	0.61 (0.53, 0.64)	0.62 (0.55, 0.59)	0.60 (0.41, 0.60)	0.53 (0.52, 0.53)

KEY FEATURES among 2000 evaluated:

Age at baseline
Hypertension
Chronic kidney disease
Heart failure
Pulmonary disease
Atrial fibrillation
Vascular disease
Fibromyalgia, chronic pain
Fatigue
Anemia
Gastrointestinal disorders

Livingston et al, Dementia prevention, intervention, and care: 2020 report of the Lancet Commission. Lancet. 2020 Aug 8;396(10248):413-446. doi: 10.1016/S0140-6736(20)30367-6. Epub 2020 Jul 30. PMID: 32738937; PMCID: PMC7392084.

Reproductive health and future dementia

Women with, versus without HDP, had a 1.4 fold higher hazard for dementia. >40% of the effect could be explained by mid-life hypertension or stroke.

	All-cause Dementia		Vascular Dementia		Alzheimer's Disease		Other Dementia	
	Number of Women; Adjusted Hazard Ratio (95% CI)							
HDP	827	1.37 (1.26, 1.50)	55	1.64 (1.19, 2.26)	178	1.04 (0.87, 1.24)	594	1.49 (1.34, 1.65)
No HDP	1596	1.00	97	1.00	410	1.00	1098	1.00

	Direct Effect	Indirect Effect	% Mediated
	Adjusted Hazard Ratio (95% CI)		
Myocardial infarction	1.40 (1.37, 1.43)	1.09 (1.06, 1.12)	24%
Ischemic heart disease	1.40 (1.37, 1.44)	1.08 (1.06, 1.11)	22%
Heart failure	1.38 (1.35, 1.42)	1.07 (1.03, 1.10)	20%
Stroke	1.27 (1.25, 1.29)	1.20 (1.18, 1.23)	49%
Chronic kidney disease	1.35 (1.32, 1.38)	1.14 (1.11, 1.17)	35%
Hypertension	1.21 (1.19, 1.24)	1.14 (1.12, 1.17)	46%
Anxiety	1.38 (1.35, 1.41)	1.10 (1.08, 1.13)	27%
Depression	1.49 (1.40, 1.57)	1.02 (0.96, 1.08)	6%

Hazard ratio models adjusted for maternal 5-year age groups, year of childbirth (within 1 year), and parity (1, 2, 3, 4, ≥5) at the time of the index pregnancy.

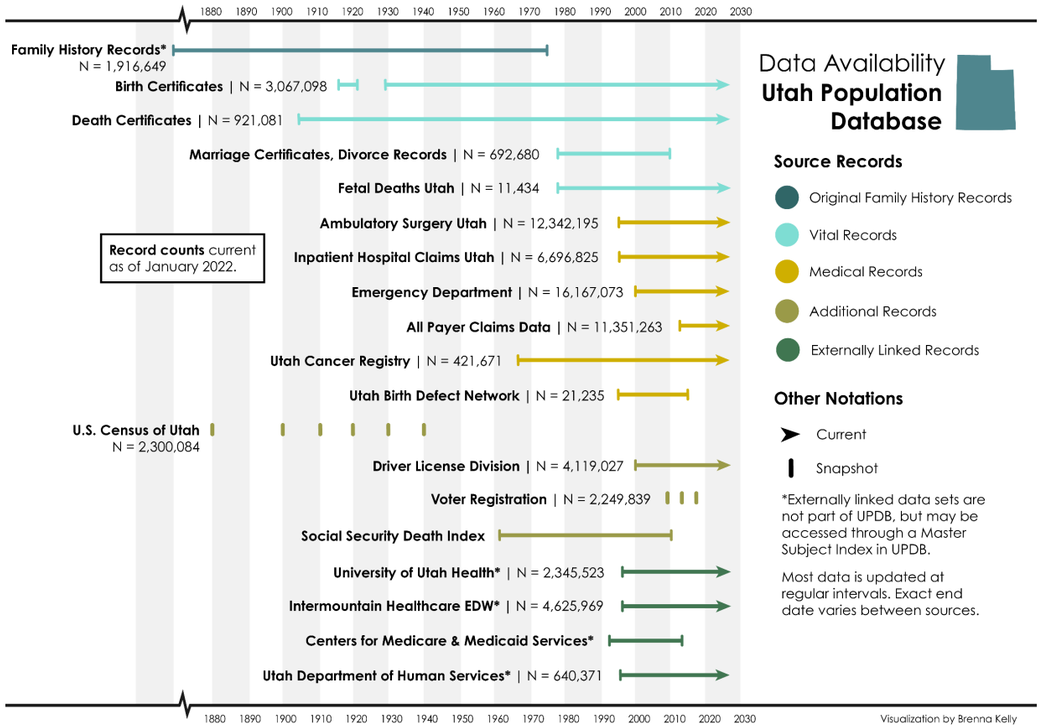
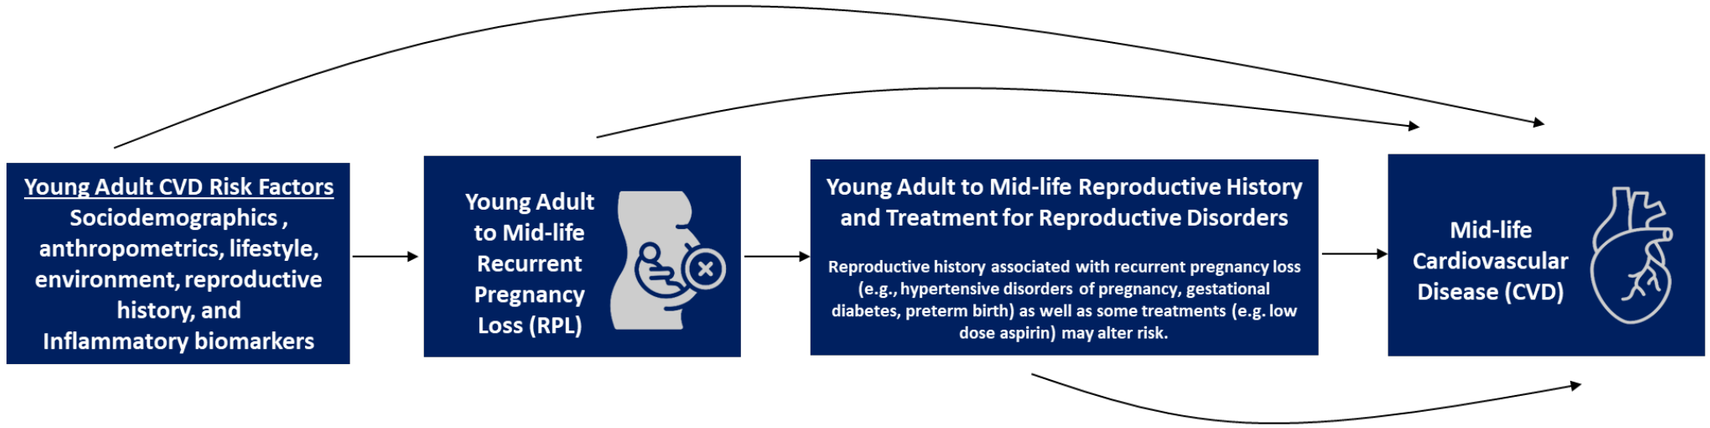
Areas for collaboration

Lifecourse epidemiology leveraging UPDB and nested research studies





Pepper Center

BENEFIT TO MY RESEARCH?

- **Clinical core:** Potential for retrospective study on reproductive health and cognitive resilience
- **Data and biomarker core:** Underlying predisposition vs reproductive events themselves cause for dementia. Novel measures of cardiometabolic risk factors and expertise on CVD and dementia outcomes.
- **Caregiver core:** Ability to support data capture of exposures and outcomes of interest

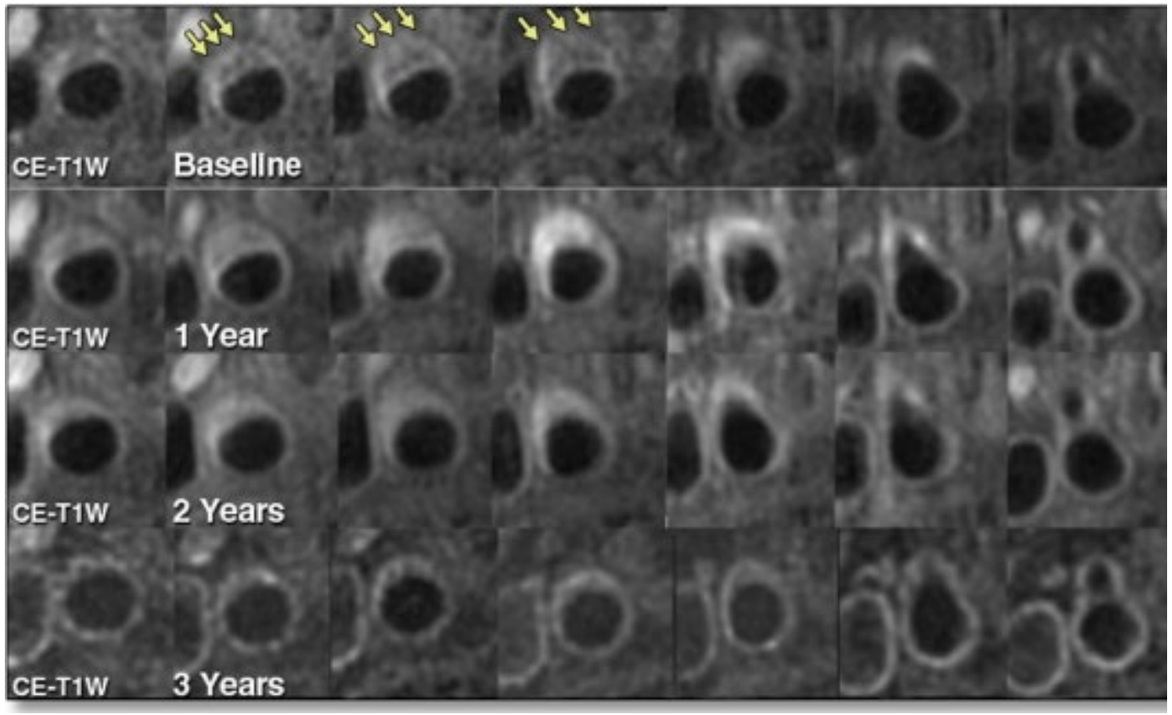
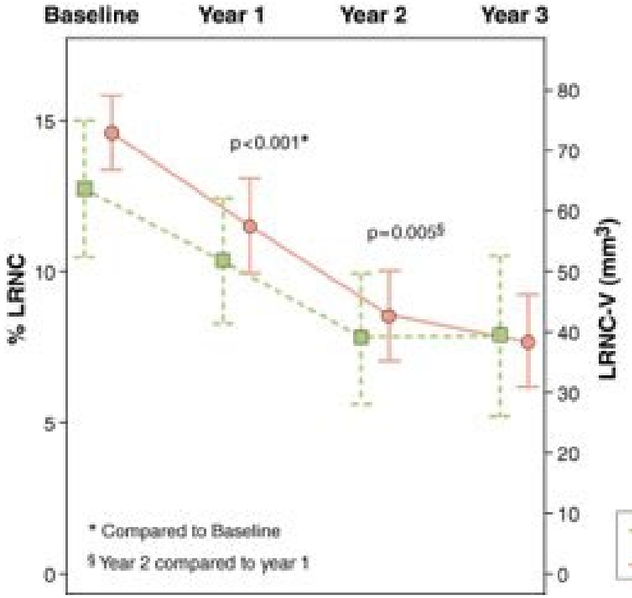
Plaque Changes over Time: Impact of Lipid Depletion Treatment Atorvastatin (CPC)

N = 33 subjects on intensive lipid therapy that included atorvastatin (10-80 mg/day)

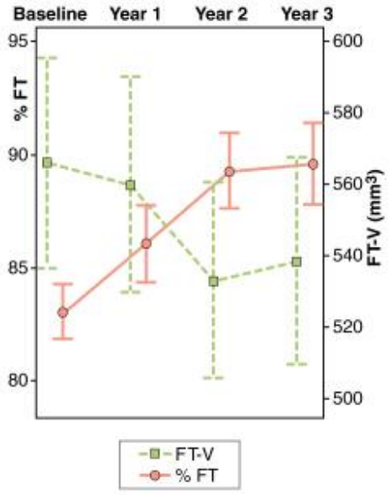


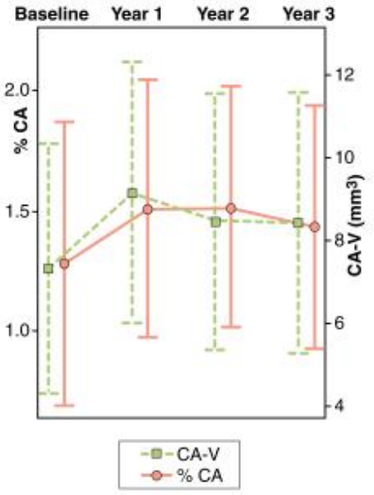
Zhao et al., *JACC Cardiovasc Imaging,* 2011;4:977-86
CPC: Carotid Plaque Composition by MRI During Lipid-Lowering

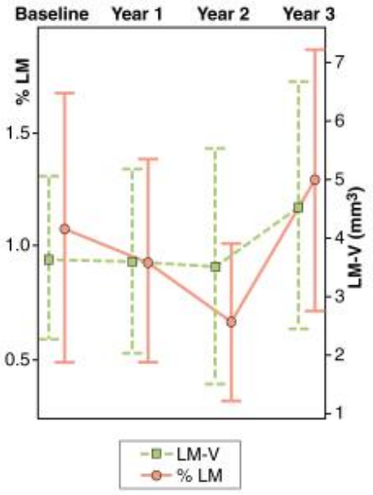


Plaque lipid depletion is observed after 1 year of treatment and continues in the second year. Regression in overall plaque burden was observed primarily at locations with a LRNC, and its time course follows plaque lipid depletion.

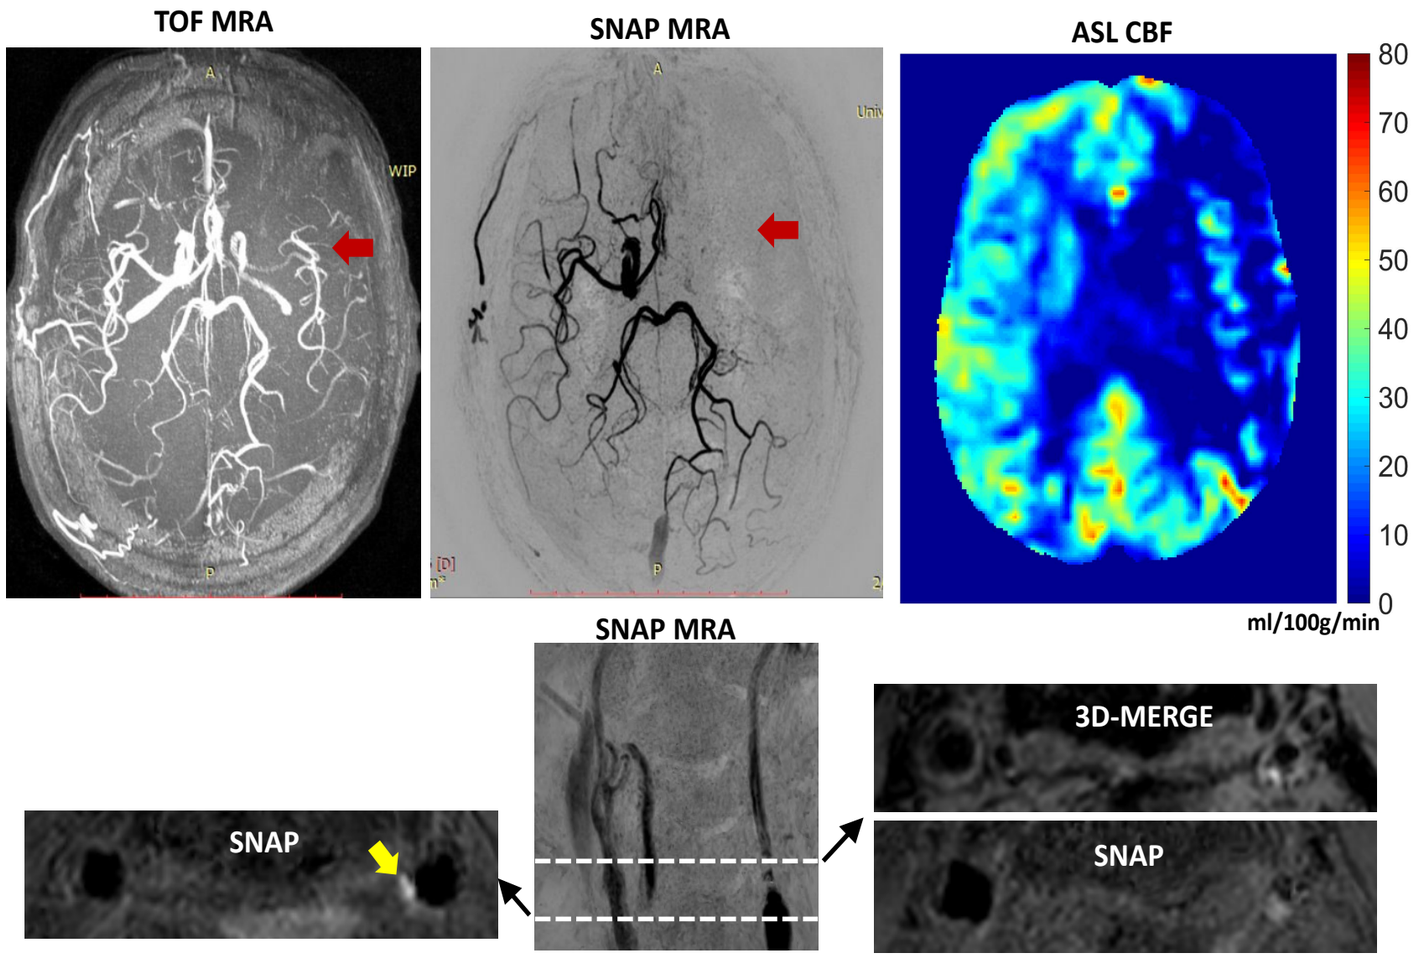
Green squares: volume
Pink circle: wall %







Cerebral Blood Flow, Vessel Wall, Brain Function



- Opportunity to study mechanisms of
  - Vascular disease progression
  - Flow in large, small artery and tissue level
  - Impact in both brain aging and chronic disease development

(ASL perfusion)
White Matter Hyperintensities

Can conditions of blood flow and vessel wall in medium-to-large arteries predict cognitive function?

> To explore the associations of intracranial artery length measured from TOF-MRA or SNAP-MRA with global cognitive function

> To compare the associations with cognitive function between different brain blood flow measuring techniques

- **29 subjects with carotid atherosclerotic disease**

- **Brain MR imaging**
  - ✓ 3D TOF
  - ✓ 3D SNAP
  - ✓ 3D arterial spin labeling (ASL)
  - ✓ 3D Phase contrast (PC)
  - ✓ 2D FLAIR (for quantifying white matter hyperintensities)

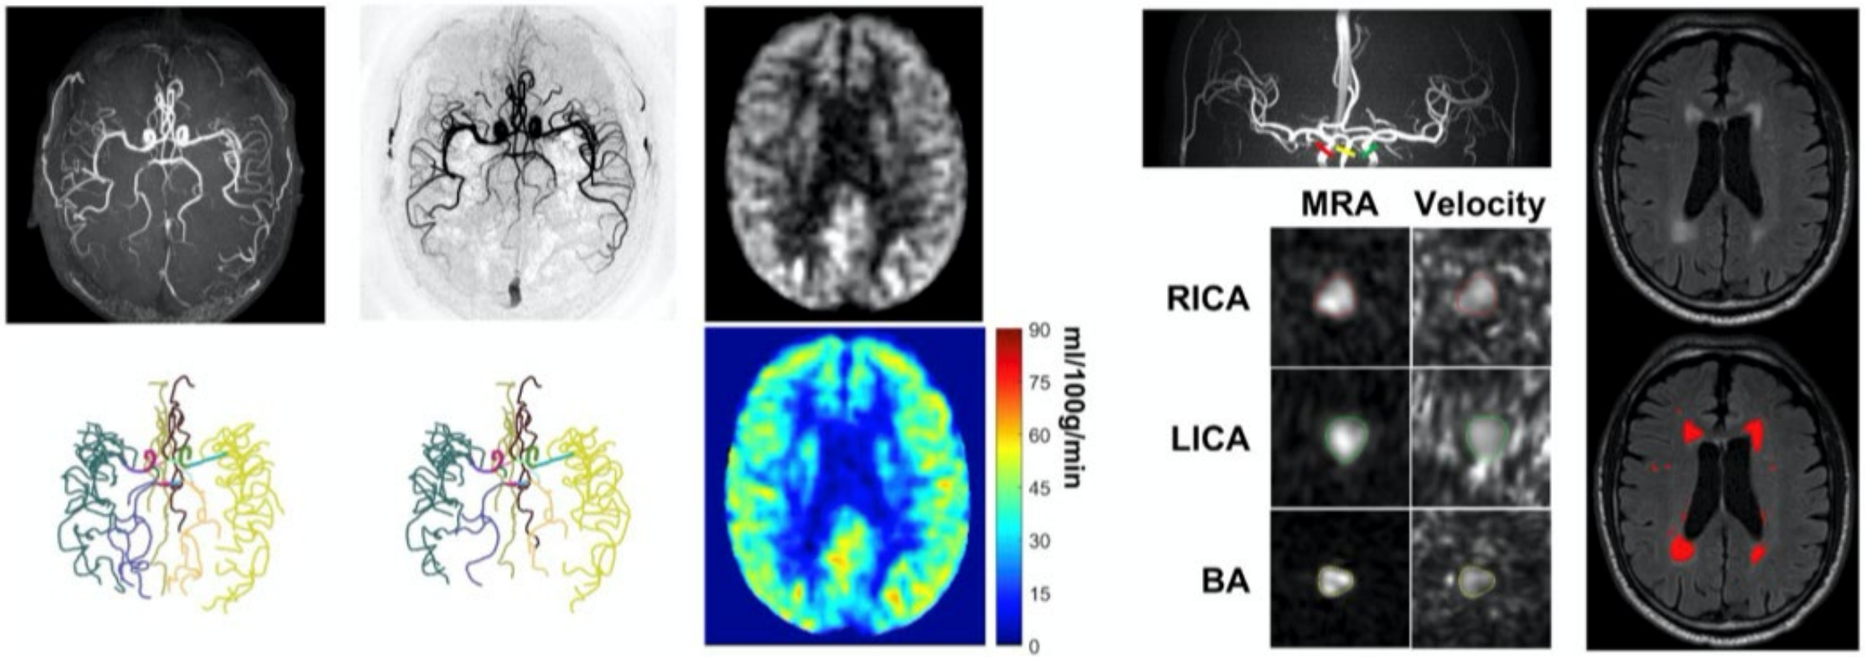
- **Global cognition was assessed using Montreal Cognitive Assessment (MoCA)**

Supported by NIH RO1 supplementary

Can conditions of blood flow and vessel wall in medium-to-large arteries predict cognitive function?

Baseline

TOF **SNAP** **ASL CBF** **3D PC** **FLAIR**



+ MoCA Test

Z Chen et al. Sci. Rep. in press, 2022

Can conditions of blood flow and vessel wall in medium-to-large arteries predict cognitive function?

Baseline result

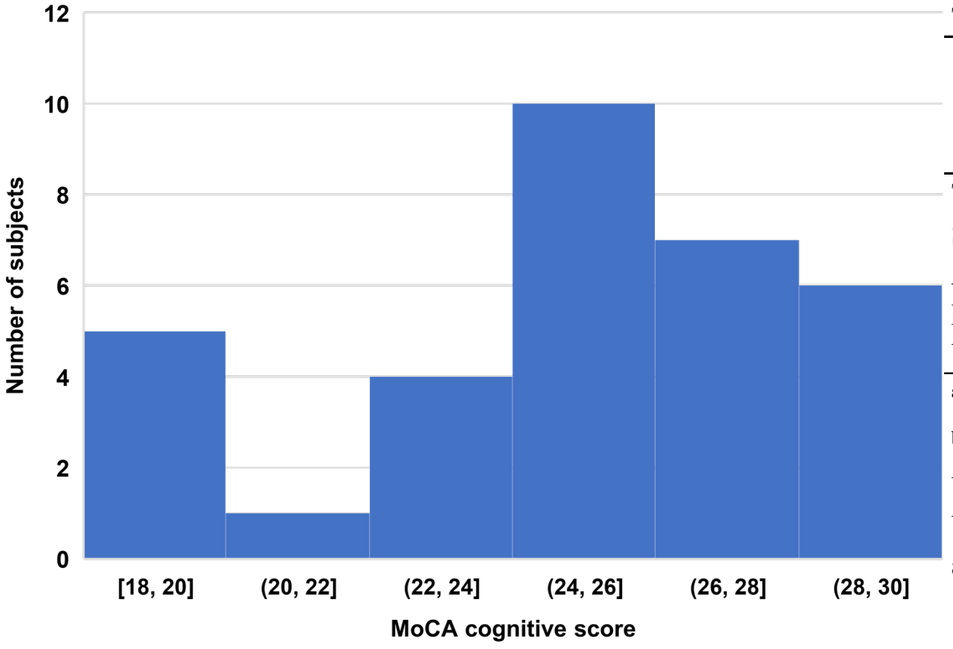


Table 2. Associations of different brain blood flow measurements, WMH volume with MoCA score (N=29[a])

Blood flow measurement	Univariable linear regression			Multivariable linear regression					
				Model 1[b]			Model 2[b]		
	β	*P*	*adjusted R²*	*β*	*P*	*adjusted R²*	*β*	*P*	*adjusted R²*
TOF artery length	0.605	**<0.001**	0.343	0.511	**0.003**	0.497	0.515	**0.003**	0.477
SNAP artery length	0.520	**0.004**	0.244	0.410	**0.040**	0.383	0.443	**0.038**	0.363
ASL CBF	0.526	**0.003**	0.250	0.309	0.097	0.341	0.329	0.097	0.316
PC CBF	0.480	**0.008**	0.202	0.352	**0.046**	0.377	0.427	**0.032**	0.372
WMH volume	-0.178	0.355	-0.004	-0.018	0.923	0.256			

[a]For one subject, the systolic blood pressure was not available. Therefore, the same size for Model 1 and Model 2 was 28.

[b]Model 1 was adjusted for age, use of antihypertensive drug and systolic blood pressure; Model 2 was Model 1 plus adjustment for WMH volume.

WMH: white matter hyperintensity; MoCA: Montreal cognitive assessment; TOF: time-of-flight; SNAP: simultaneous non-contrast angiography and intraplaque hemorrhage; ASL: arterial spin labeling; CBF: cerebral blood flow; PC: phase contrast

Can conditions of blood flow and vessel wall in medium-to-large arteries predict cognitive function?

Table 3: Correlation of carotid morphology and composition with brain lesions and MoCA

	Brain Infarct Volume (N=33) (Ipsilateral)		Brain Infarct Volume (N=33) (Whole Brain)		MoCA (N=32)

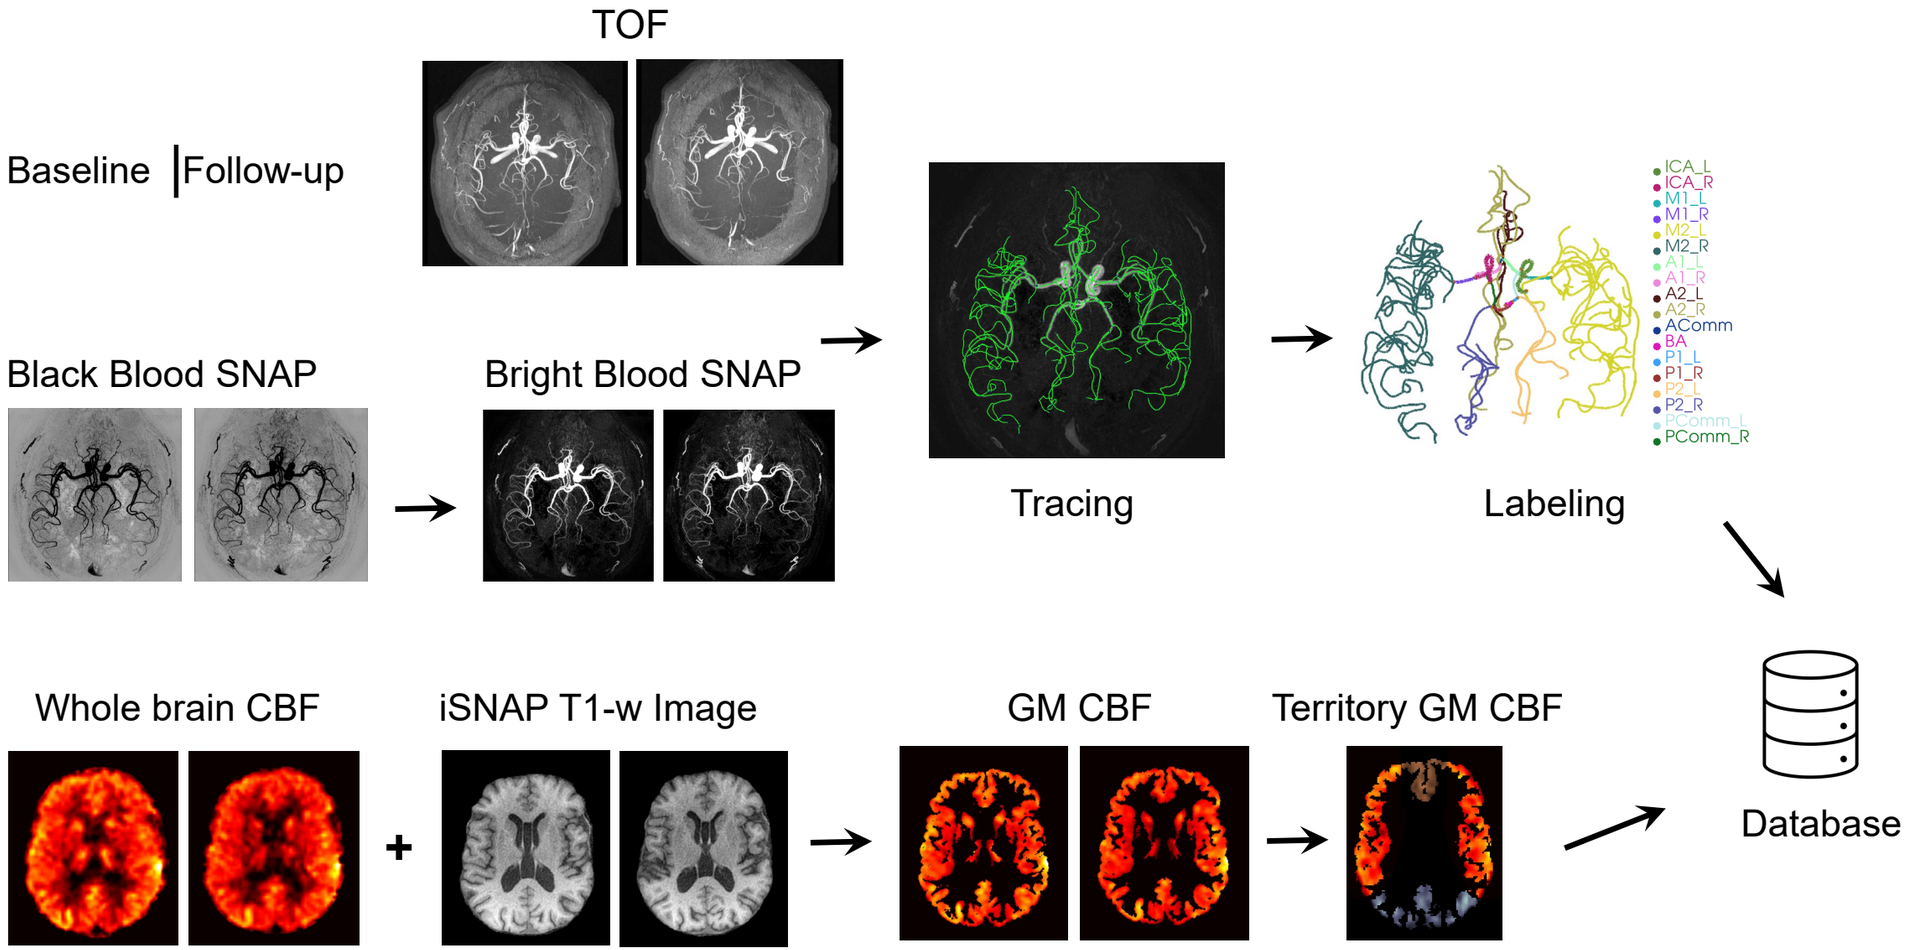
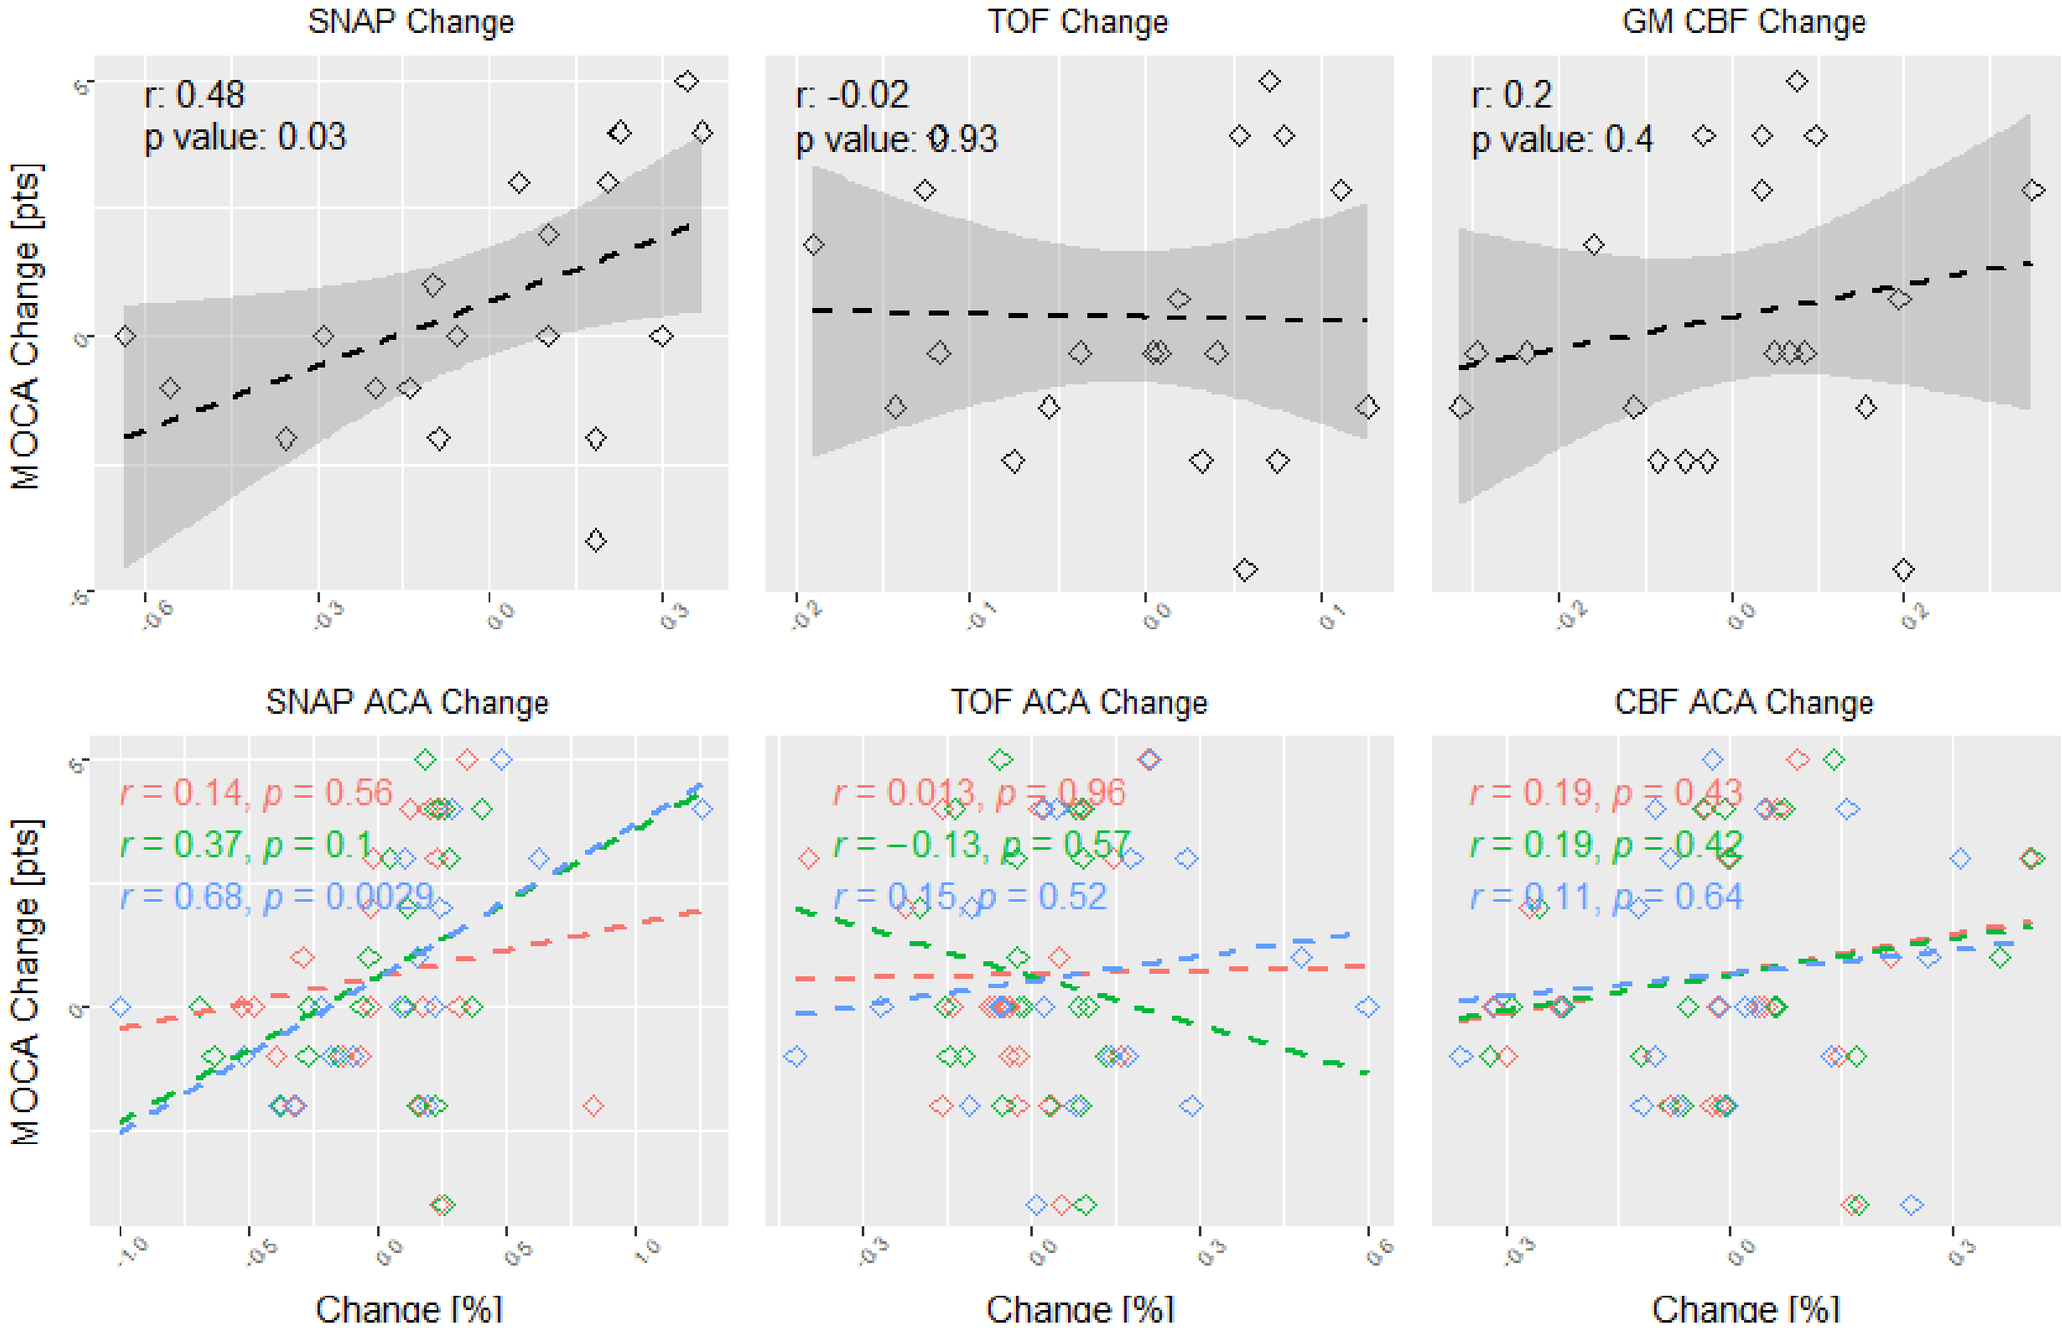
* Spearman's rank correlation coefficient. NWI: normalized wall index, WT: wall thickness, LRNC: lipid-rich necrotic core, IPH: intraplaque hemorrhage. Significant p-values bolded, trending p-values bolded and italicized.

Can conditions of blood flow and vessel wall in medium-to-large arteries predict cognitive function?

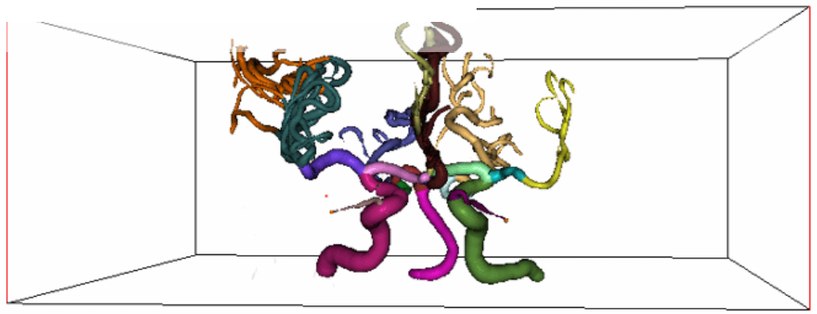
Baseline & Follow-up (1 year)

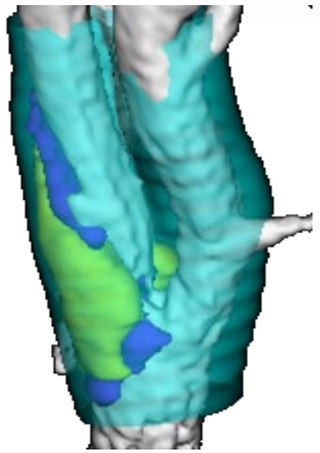




Zhang K, et al. ISMRM, 2022

Summary: Quantitative Vascular MRI Imaging's Role





A series of quantitative tools has been developed

- **Imaging sequences**
- **iCafe**
- **CASCADE – MOCHA (with new NIH funding)**
- **Quantitative measurements (3D map)**

Can be used to monitor cholesterol lowering treatment

Maybe linked to other brain maps of anatomy, function, and oxygen consumption

Can be used to study vascular health in different populations
